Historical sea ice data (1-5) show decrease winter sea ice in the Barents Sea in 1920-40s that is less decrease after 1990s. Vinje (2001) found uniform negative trend of April ice edge during 1860-1990s. Zakharov (2003) estimated the shift of ice edge to north in the Barents Sea in April about 3 degrees of latitude during 1921-38. Maximal change of ice edge is observed in summer and its influence on winter edge. Maximal correlation between monthly SAT and SIE in the Arctic is estimated in 6-11 months. The decrease of winter SIE could be a consequence of warming in 1920-40s but it could amplify one. Bitz et al (2003) considered the maintenance of ice edge under impact of external forcing 1.
