

1 Dear Dr. Bingham,

2

3 Thank you for your consideration of my revision and further suggestions to improve the  
4 manuscript. As you wrote, they were fairly minor and I very much appreciate the detail of the  
5 comments. Please see below for individual responses (indented) as to how each suggestion  
6 has been addressed.

7

8 Best wishes,

9 Allen Pope

10

11 ---

12

13 Throughout the manuscript: One instance of "bi-naming" Sermeq Kujalleq / Jakobshavn  
14 Isbrae is fine, but unnecessary for every single instance of the name in the manuscript.

15 One instance left in the abstract, first instance in the intro left as-in, and the instance in  
16 the conclusion left as-in. All others removed.

17

18 Throughout the manuscript: Using search/replace, have a thorough look through the  
19 manuscript for where you use Landsat / OLI or both terms. One you have explained the  
20 association once (in the introduction) - or possibly also in the abstract and conclusions -  
21 elsewhere you should just use one term. I'd stick to OLI.

22 I looked for all instances of Landsat and (except for the abstract, intro, and conclusion)  
23 replaced/removed "Landsat 8" so that "OLI" is the globally used term. The only exceptions  
24 are where "Landsat" was discussing the satellite series or the platform. I also followed this  
25 suggestion for Landsat 7 / ETM+.

26

27 P2 L5-6: Delete "as OLI".

28 Done.

P2, L10: Better to clarify “supraglacial” before “lakes”?

Added “supraglacial” before “lakes”

P2, L14: Replace “are” with “also”.

Done

P2, L19: Improved English would have “both” and “for” reversed here.

Done

P2, L21: Better to insert the reference at end of sentence after “Greenland”.

The reference was intentionally left in place because it specifically is about estimating depth (just as earlier in the sentence there is a reference to classification) – and all the references in that sentence are about Greenland.

P2, L27: Insert “DigitalGlobe’s” before “WorldView” (...then you don’t need DigitalGlobe again on P8 L4).

Done.

P2, L28: Capital V for WorldView; Insert comma after WorldView-3.

Both Done.

P2, L29: Insert commas before and after phrase “such as streams”.

Done.

P3, L12: Rewrite: “and that minor variations in effects of atmospheric path radiance can be ignored.”

Done.

P3, L14: Is it really necessary to include the word “successful,” or even to include the

1 references you included here to make this point? Seems possible to rephrase: “Landsat 8,  
2 launched in 2013, hosts a new multispectral sensor, named the Operation Land Imager (OLI),  
3 suitable for lake-depth estimation. The OLI has enhanced...” [then continue into existing  
4 sentence commencing L14-15]

5 Done.

6  
7 P3, L19: Insert commas before and after phrase “and narrower multispectral and  
8 panchromatic bands relative to ETM+”.

9 Done.

10  
11 P3, L20: Remove comma before “respectively”.

12 Done.

13  
14 P3, Paragraphs 2 and 3. Paragraph 3 opens with the statement “we investigate refinements on  
15 retrieval methods...using Landsat 8”. The inclusion of “refinements on” to this sentence is a  
16 little awkward, and it suggests that previous work has already used OLI to estimate  
17 supraglacial lake depths. If so, are these previous studies specifically those referred to in L17  
18 that “largely used red and green wavelengths”...? I think what is missing here is clarity on  
19 exactly what are the “published studies” referred to in L17 (i.e. are these specifically w.r.t.  
20 Landsat 8 OLI?). Depending on your answer to that, for L24-25, would it then be equally  
21 valid simply to write: “In this paper we investigate retrieval methods for supraglacial lake  
22 depth from Landsat 8 imagery” (i.e. dropping the “refinements on”?).

23 I meant to indicate that we were investigating retrieval algorithms for landsat 8, which  
24 would be refining those from Landsat 7. That was confusing, so I edited the sentence as you  
25 suggested. Also, in regard to the “published studies” I added a parenthetical “see above” for  
26 the reader to understand I was not introducing other, unreferenced studies for consideration.

27  
28 P4, L10: “both in Greenland and Antarctica”.

29 Done.

30  
31 P4,L9-14: I suggest a mild revision here for clarity: “Based upon a description of the  
32 processes that take place as light enters, passes through, and exits a lake, the method has been

1 used successfully in Greenland and Antarctica (e.g., Sneed and Hamilton, 2007; Banwell et  
2 al., 2014). Being physically-based it is easy to adjust if measurements of lake water and lake  
3 bed properties are available. However, it assumes...” [then into sentence continuing L14]

4 I have used the first part of this suggestion, but for the second half, I actually think the  
5 simpler sentence structure used in the paper is clearer for the reader.

6  
7 P5, L1-11: Just to note something strange happened with the editing tools in this section, so  
8 that it appears you intended to delete some lines – but I don’t believe this is your intention  
9 from your rebuttal comments. In your returned manuscript just have a check of what you  
10 definitely want to include.

11 Thank you for noticing this. Nothing was really inaccurate, just awkward. One  
12 extraneous sentence deleted and I think it reads fine now.

13  
14 P5, L23-26: The sentence as written doesn’t work. Should “has been used” be deleted from  
15 L23? Is “also” necessary in L25? Greenland Ice Sheet should be written with capital I and S,  
16 as in this case is used as a proper noun.

17 Capitalization made. “to derive water depth” was swapped, and the phrase was spilt  
18 into two sentences. Capitalizations made.

19  
20 Section 2.2: You don’t seem to decide whether to term the method the “spectral band ratio  
21 method”, just the “band ratio method” or the empirical method. I suggest you change  
22 instances of “band ratio” to “spectral-band ratio” (P5, L27; P6, L1) and change  
23 “empirical/band ratio” to just “empirical” on P6 L5.

24 Done.

25  
26 P6, L17: What is the current status of Pope, in review? Better not to reference work in review  
27 if publication not guaranteed.

28 It is currently being edited after fairly positive reviews and so is highly likely to be  
29 published in ESS.

30  
31 P6, L11-21: Suggested rewrite: “In summer 2010, coincident lake-bottom reflectance and  
32 depth were acquired over a supraglacial lake in West Greenland using a small remote-

1 controlled boat equipped with a compact spectroradiometer and a small sonar (Tedesco et al.,  
2 2011; 2015)". (In the sentence as written the referencing practice was strange; I don't think  
3 it's actually required to repeat the term "in situ" beyond the section title; and I think it would  
4 be good just to underscore that it's a supraglacial lake under consideration here).

5 Thank you for the suggestion. I used some of the phrasing you suggested and  
6 eliminated the "in situ" but I left the sentence in active voice rather than passive.

7

8 P7, L10: "we do not" for consistency with present tense used elsewhere.

9 "did" changed to "do"

10

11 P8, L4: Despite the reviewer query, if you wish to use 0.5 m pixel-1 here (with -1  
12 superscript), I find that acceptable, even preferable.

13 Reinstated.

14

15 P8, L4: Remove "DigitalGlobe's" here (more logical to put this, if needed, on p2 as advised  
16 above).

17 Done.

18

19 P8, L12: Should "90%" come before "horizontal"?

20 Nope, it is correct as is.

21

22 P8, L22: Insert comma after "Greenland".

23 added

24

25 P9, L1: Despite reviewer comment, "blunders" sounds informal to me. I would maintain this  
26 as "errors".

27 Replaced.

28

29 P10, L9: rearrange "still to perform".

30 Infinitive re-joined.

31

1 P10, L5-26: Why do you need to add the day-of-year number after each date? I don't see you  
2 using these day numbers in any of the figures, so is there any other cross-referencing  
3 requirement?

4 Days of year removed. They were there when an earlier version of the figure just had  
5 DOY and it was an oversight to not remove them. Thanks!

6  
7 P10, L28: I think a rewritten sentence, with just some minor elements of reinforcing data  
8 sources/locations, might just convey the link better here: "For both of our case study regions,  
9 northwest and southwest Greenland, we difference all overlapping areas of OLI-derived lake  
10 depths and WorldView-derived DEMs."

11 Thank you – suggestion used.

12  
13 P10, L30: Replace "methods" with "results".

14 Done.

15  
16 P11, L24: I think "time series" is two words...

17 Word spell check agrees!

18  
19 P12, L3-4: Insert commas before and after "which transects the lower Sermeq Kujalleq  
20 (Jakobshavn Isbrae)" and reverse "both of" in L4.

21 Done and done.

22  
23 P12,L6: Pretty sure you mean "latitude", not "altitude" here.

24 Indeed. "altitude" changed to "latitude"

25  
26 P12, L19-20. The sentence is ambiguously written to implicate slow flow in less available  
27 meltwater. Suggest: "At higher elevations, slow flow leads to low-amplitude ice surface  
28 topography thus shallower depressions, and there is also less available meltwater to fill ice-  
29 surface depressions."

1           Removed used. The studies which should be referenced are all discussed in the section  
2 above, as indicated by the introductory phrase. The sentence has been amended to: "For all  
3 three studies, the regressed  $g$ 's are much closer to the updated lab-based  $g$ 's (see Sect. 2.1 &  
4 Supplementary Material) than those used in the studies."

5

6 P16, L8: "...common both in..."

7           Done.

8

9 Section 5.4: I am rather unconvinced of the worth of this section. It does not make much use  
10 of the results generated by the paper itself other than emphasising the potentially short  
11 duration of lakewater residence times. Apart from that it seems mostly to be rationale-for-  
12 study, which seems out of place this late in the paper. In my view, in its brevity it also rather  
13 oversimplifies the hydrological system, and only presents the case for how supraglacial lakes  
14 may enhance ice dynamics by enabling episodic injections of floodwater to the ice base,  
15 and/or increase heat transfer to the bed. The second process can only be a secondary effect,  
16 while there is some counter evidence to the former in the literature, especially if one is  
17 considering the degree to which supraglacial melt inputs affect ice dynamics over annual  
18 timescales, i.e. the timescales that really matter when trying to determine if melt increases  
19 may           accelerate           Greenland's           dynamic           response.  
20 I think you already did a nice, concise job in the very first paragraph of the paper of saying  
21 why studying supraglacial lakes is important, and I would recommend your paper would stand  
22 very well without this final section to the discussion.

23           Thank you for this helpful suggestion. I do feel that including the information about  
24 potentially short duration of lakewater residence times is a new contribution that deserved to  
25 be included, but I take your point about the rest of the section. Therefore, I have moved most  
26 of the text from the 1<sup>st</sup> paragraph to the results section on Sermeq Kujalleq and completely  
27 deleted           the           rest           of           this           discussion           section.

28

29 P17, L13: Suggest you expand OLI to full name for its first mention in the conclusions, as  
30 some readers may have skipped to here pretty quickly and need the reminder/introduction to  
31 the abbreviation.

1 Done.

2

3 Figure 1 caption: As you have the Howat et al. (2014) reference, you don't need "courtesy  
4 BPRC Glacier Dynamics Research Group, Ohio State University" in the final line.

5 Removed the courtesy, added a new data citation because the data are now stored at  
6 NSIDC.

7

8 Figure 2: The caption for part (a) suggest part (a) should pertain to ETM+ but it appears (at  
9 least from the annotation in the top right) to pertain to OLI. The reverse issue is true for part  
10 (b) and the caption for part (b). Unless I missed something about what these figures are  
11 showing, there seems to be a little mix-up. I do think the annotations are good in principle  
12 though, so can similar text annotations for OLI-C and OLI-G be added to parts (c) and (d)?

13 The confusion was that the letter annotation is AFTER the text rather than before. I  
14 have changed commas to semicolons to clarify this.

15

16 Figure 3: Somewhere in the caption or legend it would be nice just to have the clarification  
17 that the bands are "Landsat 8 OLI" bands. Just for the reader who may jump straight to  
18 diagrams.

19 "derived using OLI" added to the end of the first sentence in the caption.

20

21 Figure 4 caption, L10: use hyphenation throughout "in-situ-regressed".

22 Done

23

24 Figure 4 label y axis: Capital D for both instances of "Derived"

25 Done.

26

27 Figure 5: Requires a clarification in the caption as to what the small text annotations  
28 associated with each line refer. Presumably path/row number from WRS-2/Irons et al., 2012 –  
29 but this needs to be written explicitly into the caption.

30 "(as indicated by WRS-2 path/row annotations)" added to the caption

31

1 Figure 6: Re the sentence “A histogram of lake depths (a) shows many shallow lakes, many  
2 lakes reaching depths of ~3 m, and a maximum lake 6 depth of ~6 m”. What is shallow? Why  
3 identify 3 m on this curve in particular? I think the only valid part of this sentence is the  
4 identification of maximum lake depth – but even if all statements were valid, the sentence is  
5 anyway unnecessary for a figure caption as readers should get the information they desire  
6 simply by looking at the graph itself. I would rewrite this whole sentence simply as “(a)  
7 Histogram of lake depths”. Your caption to part (b) is also strangely composed. I suggest  
8 rewriting as “(b) Lake-depth by pixel distribution.”  
9 Finally, re this caption, I can’t follow what is meant by the reference to hypsometry/GIMP  
10 DEM. Can you clarify?

11 The 3m point is identified in particular because there is an inflection point on the  
12 histogram which I thought was worthwhile noting, but your point is taken and the caption has  
13 been shortened. I have also simplified the caption to part (b) as “Maximum lake depth in 1-m  
14 elevation bins as derived from the GIMP DEM (Howat et al., 2014, 2015).”

18  
19 **Abstract**

20 Liquid water stored on the surface of ice sheets and glaciers impacts surface mass balance, ice  
21 dynamics and heat transport. Multispectral remote sensing can be used to detect supraglacial  
22 lakes and estimate their depth and area. In this study, we use in situ spectral and bathymetric  
23 data to assess lake depth retrieval using the recently launched Landsat 8 Operational Land  
24 Imager (OLI). We also extend our analysis to other multispectral sensors to evaluate their  
25 performance with similar methods. Digital elevation models derived from WorldView stereo  
26 imagery (pre-lake filling and post-drainage) are used to validate spectrally derived depths,  
27 combined with a lake edge determination from imagery. The optimal supraglacial lake depth  
28 retrieval is a physically based single-band model applied to two OLI bands independently (red

1 and panchromatic) that are then averaged together. When OLI- and WorldView-derived  
2 depths are differenced, they yield a mean and standard deviation of  $0.0 \pm 1.6$  m. This method  
3 is then applied to OLI data for the Sermeq Kujalleq (Jakobshavn Isbrae) region of Greenland  
4 to study the spatial and intra-seasonal variability of supraglacial lakes during summer 2014.  
5 We also give coefficients for estimating supraglacial lake depth using a similar method with  
6 other multispectral sensors.

Allen Pope 11/12/2015 18:06

Deleted: as OLI

7

## 8 1 Introduction & Rationale

9 Supraglacial lakes in Greenland play a crucial role in the ice sheet's hydrological system.  
10 Together with supraglacial streams (Smith et al., 2015), supraglacial lakes temporarily store  
11 large quantities of meltwater which can promote the opening of conduits to the bed through  
12 hydrofracture (Das et al., 2008; Phillips et al., 2013; Selmes et al., 2011; Tedesco et al., 2013)  
13 and thus influence ice dynamics (Joughin et al., 2013; Parizek and Alley, 2004; Sundal et al.,  
14 2011; Zwally et al., 2002). Supraglacial lakes also influence surface heat fluxes by storing  
15 latent heat near the surface of the ice sheet (Koenig et al., 2015). Finally, supraglacial lakes  
16 contribute to multiple positive feedback processes, including ice shelf disintegration in  
17 Antarctica (Banwell et al., 2013; Glasser and Scambos, 2008) and melt-albedo interactions  
18 (Leeson et al., 2015).

Allen Pope 11/12/2015 18:07

Deleted: are

19 Several multispectral remote sensing tools and methods exist both for classifying (Johansson  
20 and Brown, 2013; Leeson et al., 2013; Sundal et al., 2011) and estimating the depth of  
21 supraglacial lakes (Sneed and Hamilton, 2007) in Greenland. MODIS (the MODerate  
22 Resolution Imaging Spectroradiometer) is able to provide large spatial coverage (2,330 km  
23 swath width), moderate resolution (~250 m) images of Greenland twice per day (e.g., Box and  
24 Ski, 2007; Fitzpatrick et al., 2013). ASTER (the Advanced Spaceborne Thermal Emission and  
25 Reflection Radiometer, e.g. Sneed and Hamilton, 2007) and Landsat (e.g. Banwell et al.,  
26 2014; Morriss et al., 2013) have higher spatial resolution (10-30 m) but lower spatial coverage  
27 and fewer acquisitions (16 day repeat). Commercial sensors, such as DigitalGlobe's  
28 WorldView-2 and WorldView-3, provide high resolution multispectral measurements (~2 m)  
29 that can be used to image small water features, such as streams, over smaller areas (17 km  
30 wide swath), at both high temporal and spatial resolution (Chu, 2014; Legleiter et al., 2014;  
31 Smith et al., 2015). However, commercial imagery is collected largely 'on demand' and cloud

Allen Pope 11/12/2015 18:08

Deleted: both

Allen Pope 11/12/2015 18:10

Deleted: Worldview

1 cover can still be a confounding factor. Here we provide the first regional scale validation of  
2 supraglacial lake depth estimation methods with all of the above multispectral sensors.

3 Lake depth retrieval is based upon the understanding that deep water absorbs more energy  
4 than shallow water and therefore will have lower reflectance of solar radiation. Some methods  
5 use one band for a reflectance-depth relationship, while others use a ratio of reflectances from  
6 two different spectral bands (see Sect. 2). Satellite retrieval of supraglacial lake depth is  
7 confounded by difficulty measuring the true reflectance of dark/deep lakes, assumptions  
8 inherent in the method about minimal quantities of suspended and dissolved matter in lake  
9 water, the requirement for a smooth (i.e., not wind-roughened) lake surface, and  
10 homogeneous and low-slope lake bottoms (Sneed and Hamilton, 2011). In this study we  
11 assume that it is possible to apply locally calibrated coefficients to broad areas (e.g., Legleiter

12 et al., 2014), and that minor variations in effects of atmospheric path radiance can be ignored,  
13 Landsat 8, launched in 2013, hosts a new multispectral sensor, named the Operation Land  
14 Imager (OLI), suitable for lake-depth estimation. The OLI has enhanced radiometric  
15 resolution (12-bit vs. 8-bit), a higher signal to noise ratio, and an expanded dynamic range  
16 compared to Landsat 7's Enhanced Thematic Mapper Plus (ETM+). While published studies  
17 (see above) have largely used red and green wavelengths, OLI's two additional bands  
18 (coastal, 0.433-0.453  $\mu\text{m}$ ; and cirrus, 1.360-1.390  $\mu\text{m}$ ), and narrower multispectral and  
19 panchromatic bands relative to ETM+, will provide more spectral information and more  
20 unique (i.e., less auto-correlated) reflectance values, respectively. These properties lead to  
21 improvements for lake depth retrieval methods based on band ratios. Furthermore, an  
22 increased scene collection rate by Landsat 8 will lead to more opportunities to observe ice  
23 sheets and their supraglacial lakes.

24 In this paper we investigate retrieval methods for supraglacial lake depth from OLI data. We  
25 use in situ spectral measurements from a supraglacial lake in Greenland to emulate satellite  
26 reflectance and compare them with depth data from the same lake to test several techniques to  
27 extract lake depth. We then apply the best methods to OLI imagery for case study areas in  
28 Northwest Greenland and the Sermeq Kujalleq (Jakobshavn Isbrae) area. We validate depth  
29 estimates using digital elevation models (DEMs) derived from stereo sub-meter imagery. We  
30 discuss best practices for deriving lake depths using OLI and the implications of these  
31 conclusions for other multispectral sensors. Analysis of 2014 imagery yields information  
32 about supraglacial lake size, distribution, and seasonal behavior.

## 2 Methods

### 2.1 Physically Based Lake Depth

The depth of a supraglacial lake can be approximated as (after Philpot, 1989):

$$z = [\ln(A_d - R_\infty) - \ln(R_{lake} - R_\infty)] / g \quad (1)$$

where  $z$  is lake depth in meters,  $A_d$  is the lake bottom albedo,  $R_\infty$  is the reflectance of optically deep water,  $R_{lake}$  is the reflectance of a lake pixel, and  $g$  is related to the losses in upward and downward travel through the water column (units:  $\text{m}^{-1}$ ). Based upon a description of the processes that take place as light enters, passes through, and exits a lake, this method has been used successfully both in Greenland and Antarctica (e.g., Banwell et al., 2014; Sneed and Hamilton, 2007). It is physically based and therefore easy to adjust if measurements of lake water and lake bed properties are available. However, this method assumes that lake water has little to no dissolved or suspended matter and would be severely impacted by surface waves (wind-driven ripples, choppy waves, etc.). Additionally, it requires that the lake bottoms have low slopes and a homogeneous albedo (Sneed and Hamilton, 2011). While most of these assumptions hold for supraglacial lakes in Greenland (Sneed and Hamilton, 2011), lake bottoms are known to be too inhomogeneous to support the approach generally. In addition, optically deep water (i.e., deep lakes or ocean where the upwelling radiance originates from the water column without any bottom signal contribution) is not always available in inland Landsat scenes. The effects of these shortcomings on supraglacial lake depth retrievals have not been quantified.

In this study, for application to OLI imagery,  $R_\infty$  was obtained from dark ocean or lake water in the scene, following Sneed and Hamilton (2007, 2011). If no coast was available in the scene containing the lake,  $R_\infty$  was obtained from another scene further along the path (with an implicit assumption of similar atmospheric conditions). The parameter  $g$  was calculated following earlier studies (Smith and Baker, 1981; Sneed and Hamilton, 2007), but with an updated absorption coefficient from Pope and Fry (1997, Table 3); for more details, see the Supplementary Material.

$A_d$  was obtained from the reflectance immediately outside identified lake areas. However, in order to test this approximation for  $A_d$ , we also solve for lake bottom albedo rather than assuming it to be the same as the surrounding ice. We use spectral mixture analysis (Lillesand et al., 2007) to define a fractional coverage of ice ( $r_i$ ) and cryoconite ( $r_c = 1 - r_i$ ) in each lake

1 bottom pixel. To create a determinable equation after introducing this new unknown ( $r_i$ ), we  
 2 use reflectances from two OLI spectral bands (indicated with subscripts 1 and 2, below), and  
 3 derive end-member reflectances for ice ( $R_{i1}$  or  $R_{i2}$ ) and cryoconite ( $R_{c1}$  or  $R_{c2}$ ) using glacier  
 4 reflectance spectra from Pope and Rees (2014b) in conjunction with OLI spectral response  
 5 functions in both bands (Barsi et al., 2014). We input these parameters into Equation 1 and  
 6 then combine the expressions by equating lake depth, thus obtaining:

$$7 \left[ \frac{r_i(R_{i1}-R_{c1})+R_{c1}-R_{\infty 1}}{R_{w1}-R_{\infty 1}} \right] g_2 = \left[ \frac{r_i(R_{i2}-R_{c2})+R_{c2}-R_{\infty 2}}{R_{w2}-R_{\infty 2}} \right] g_1 \quad (2)$$

8 After Eq. 2 is solved for  $r_i$ , the bottom albedo for one OLI spectral band can be calculated and  
 9 subsequently used to compute lake depth:

$$10 A_{d1} = r_i R_{i1} + (1 - r_i) R_{c1} \quad (3)$$

11

$$12 z = \frac{\log(R_{lake1}-R_{\infty 1})-\log(A_{d1}-R_{\infty 1})}{-g_1} \quad (4)$$

13 where  $R_{lake1}$  is water leaving reflectance (as in Eq. 1) for the first band in the pair used and  $z$  is  
 14 lake depth.

15 [[Table 1]]

## 16 2.2 Empirically Derived Lake Depth

17 The second method we consider uses spectral band ratios to derive water depth. It has been  
 18 used in shallow marine settings (e.g., Dierssen et al., 2003) and alluvial rivers (e.g., Legleiter  
 19 and Overstreet, 2012), and has been adapted for use on the Greenland Ice Sheet (Legleiter et  
 20 al., 2014). While the physically based method above is highly dependent on  $A_d$  and  $g$ , earlier  
 21 studies show that the spectral band ratio method is expected to be more robust to variations in  
 22 these parameters (Legleiter et al., 2009; Stumpf et al., 2003). This is because the method  
 23 relies on relative behavior in two different wavelengths, as opposed to absolute optical  
 24 behavior.

25 This spectral band ratio method employs an empirically derived quadratic formula to relate  
 26 lake depths to the ratio of the reflectance of two spectral bands ( $R_1$  and  $R_2$ ):

$$27 z = a + bX + cX^2 \quad (5)$$

$$28 X = \ln(R_1/R_2) \quad (6)$$

Allen Pope 11/12/2015 18:09

**Deleted:** We then use these coefficients and end-members of ice and cryoconite reflectances to calculate the lake bottom albedo ( $A_d$ ).

1 This empirical method requires the derivation of calibrated coefficients (i.e.  $a$ ,  $b$ , and  $c$ ), and  
2 coefficients vary depending on which sensors and bands are used (Legleiter et al., 2014). We  
3 calculate these coefficients using a known set of reflectances and depths (from in situ  
4 measurements, see Sect. 3.1 & 4.1).

### 5 3 Data

6 We use three datasets in this study: in situ reflectance spectra and lake depth, OLI imagery,  
7 and DEMs derived from stereo WorldView imagery. We use in situ data to test different lake  
8 retrieval methods for a range of spectral bands. Then, we calculate lake depth with a range of  
9 the most promising methods using OLI imagery. We then use WorldView DEMs to validate  
10 the OLI-derived lake depths. The detailed workflow of software (including MATLAB and  
11 shell scripts that call GDAL utilities) used for data analysis and presentation in this study will  
12 be fully described and documented in a subsequent paper (Pope, in review).

#### 13 3.1 In Situ Data

14 In summer 2010, Tedesco and Steiner (2011) used a small remote-controlled boat equipped  
15 with a compact spectroradiometer and a small sonar to collect coincident lake-bottom  
16 reflectance and depth over one lake in West Greenland (Tedesco et al., 2015). We use 2226  
17 unique sample points from that study to evaluate the performance of the remote sensing  
18 methods described above. Field spectra are convolved to account for the spectral response of  
19 the spaceborne sensors as follows:

$$20 r_{nb} = \frac{\int_0^{\infty} r(\lambda)R(\lambda)d\lambda}{\int_0^{\infty} R(\lambda)d\lambda} \quad (7)$$

21 where  $r_{nb}$  is the narrowband reflectance,  $r(\lambda)$  is the spectral reflectance,  $R(\lambda)$  is the relative  
22 spectral response (Barsi et al., 2014), and  $\lambda$  is the wavelength. In order to emulate sensor  
23 dynamic range and radiometric resolution, we impose minimum and maximum reflectances  
24 and round reflectance values to the appropriate precision (i.e., 8-bit or 12-bit; see Pope and  
25 Rees, 2014a). We then regress the convolved reflectances and in situ depth measurements to  
26 test the goodness of fit of the physically based relationship presented in Eq. 1 and the  
27 empirical method described in Eqs. 5 and 6.

### 3.2 OLI Imagery

Landsat 8 launched on 11 February 2013 and became operational on 30 May 2013 (Roy et al., 2014). OLI collects spectral data gridded at 30 m spatial resolution (15 m for panchromatic data). We calculate top-of-atmosphere (TOA) reflectance using calibration coefficients provided in the image metadata and a solar elevation cosine correction (USGS, 2013). Based on a sensitivity analysis of path radiance to water vapor and ozone using an atmospheric radiative transfer model (see Sect. 5), we do not atmospherically correct the images.

We choose two study areas for applying OLI imagery (see Fig 1). One site located in northwest Greenland (including Sverdrup Gletsjer, Dietrichson Gletsjer, Sermersuaq, and Kjer Gletsjer, on Melville Bay; 56.2966-58.7186°W, 74.9685-75.7808°N) is an area with a high concentration of lakes and was imaged four times by OLI throughout summer 2013. A larger region farther to the south is examined using all available OLI scenes collected over the Sermeq Kujalleq region in West Greenland in 2014. For a list of all OLI scenes used in this study, see Table S2.

[[Fig. 1]]

Using the calculated TOA reflectances, we define supraglacial lake extent using the ratio between the blue and red bands (Banwell et al., 2014; Box and Ski, 2007). However, since OLI bands are slightly different from those of past sensors, we could not use published thresholds for extent. We set the threshold for this ratio at 1.5 (vs. 1.05-1.25 for ETM+ in Banwell et al., 2014) based upon visual comparison with the imagery. We then visually inspected and manually adjusted the threshold mask to remove coastal water areas (i.e., not on the ice sheet) and clouds. Although Leeson et al. (2013) describe such thresholding as too coarse for low resolution imagery (i.e. MODIS), they do acknowledge its utility for higher resolution imagery (i.e. ASTER, Landsat, etc.). We remove regions four pixels or smaller (i.e. small lakes likely comprised solely of mixed pixels) or less than two pixels wide (i.e. linear features likely to be channels, not lakes) from the lake mask.

We interpolate the lake mask using a nearest neighbor algorithm, in order to apply the physically based method to the higher resolution panchromatic band. Where both panchromatic and spectral bands were used together, we bilinearly interpolate the panchromatic image to 30 m resolution.

### 3.3 WorldView DEMs

We use submeter (~0.5 m pixel<sup>-1</sup>) stereo imagery from WorldView-1 and WorldView-2 to create DEMs of lake areas both before filling and after drainage. Similar validation for ASTER has been carried out with airborne LiDAR from before lake drainage (Georgiou et al., 2009), and for estimating lake drainage volumes (Stevens et al., 2015). We generate the high resolution WorldView DEMs using the open source NASA Ames Stereo Pipeline tool (Moratto et al., 2010; Shean et al., 2015). For both the Sermeq Kujalleq and northwest sites, we use DEMs from six different days, for a total of 12 DEMs (see Table S2).

WorldView-1 image data have a geolocation accuracy of better than 4.0 m horizontal 90% circular error of probability and WorldView-2 better than 3.5 m (DigitalGlobe, 2014). Thus, the imagery and DEMs are more precisely positioned than the 15-30 m OLI.

The vertical accuracy of the derived DEM products is less than 5.0 m 90% vertical error of probability with submeter relative vertical precision (Mitchell, 2010). Differencing a WorldView DEM with an Airborne Topographic Mapper LiDAR profile over a pronounced basin in northeast Greenland provided a standard deviation over the spread of elevations of 0.25 m. Considered conservatively, differencing one WorldView DEM with a second DEM collected one year later provided a standard deviation of 0.58 m for the elevation differences (Willis et al., 2015). Stacks of 13 and 17 overlapping WorldView-1 and WorldView-2 DEMs over Summit Station and Tracy Glacier, Greenland, provide absolute vertical accuracy estimates of ~2.0-3.0 m relative to airborne LiDAR measurements (~10 cm accuracy). After removing absolute horizontal and vertical offsets from all DEMs, the relative vertical accuracy (1-sigma) for the stack was ~15-30 cm (Shean et al., 2015).

We resample the DEMs to the same grid as OLI imagery using cubic interpolation. The OLI and WorldView acquisitions are from different dates, and although lake basins do ablate during the summer, this should not have significant impact on the results presented here, because most supraglacial lakes in Greenland remain fixed over bedrock-controlled surface depressions (Lampkin and VanderBerg, 2011). Using the lake mask, we identify a shoreline for a given date (see Sect. 3.2), which is then used to derive lake depth. We remove outliers of impossibly shallow (i.e. negative depth) or deep (>65 m) values as errors in the DEM. In addition, we remove lakes having a standard deviation in lake elevation along the shoreline of larger than 1.5 m. These steps also mitigated any potential bias caused by temporal offset between DEM and spectral depth measurements.

## 3 **4 Results**

### 4 **4.1 In Situ Results**

5 The results (Table 1) of depth-reflectance regressions for all methods are shown in Fig. 2. We  
6 base the bands tested here using in situ data upon those identified in the literature (e.g., Box  
7 and Ski, 2007; Sneed and Hamilton, 2007; Tedesco and Steiner, 2011), as well as the OLI's  
8 new coastal band and the significantly narrowed panchromatic band (0.500-0.680  $\mu\text{m}$ , at 15m  
9 spatial resolution). ETM+ high and low gain results are virtually indistinguishable, and so  
10 only low gain results are shown here. For each regression, we use the correlation coefficient  
11 ( $r$ ) and the root mean square error (RMSE, relative to sonar depths) to assess the performance  
12 of each method. The results of the physically based method show that the OLI blue and  
13 coastal bands do not perform well relative to other bands (RMSE of 3.10 m and 11.03 m,  
14 respectively;  $r$  of 0.29 and 0.05, respectively). The OLI Band 3 (green, 0.525-0.600  $\mu\text{m}$ ; 0.78  
15 m,  $r = 0.78$ ) performs as well as legacy ETM+'s Band 2 (green, 0.525-0.605  $\mu\text{m}$ ; 0.77 m,  $r =$   
16 0.79). Finally, both OLI Band 4 (red, 0.640-0.670  $\mu\text{m}$ ) and Band 8 (panchromatic, 0.500-  
17 0.680  $\mu\text{m}$ ) bands outperform their analogous ETM+ bands (RMSE of 0.28 m and 0.63 m,  
18 respectively;  $r$  of 0.96 and 0.84, respectively).

19 [[Fig. 2]]

20 Red light attenuates more strongly in water than green or blue light. So, for the same lake  
21 depth, there will be a larger (and easier to measure) change in net reflectance for red  
22 wavelengths than shorter wavelengths. However, the rapid attenuation of red light means that  
23 only shallower lakes may be measured in this band. The maximum in situ lake depth  
24 measurement is  $\sim 5$  m, well within the red light limit, but deeper lakes may exist in the overall  
25 study area. We address this issue below by using many Landsat scenes and WorldView  
26 DEMs.

27 We investigate the two-band physically based method (where  $A_d$  was calculated) with a range  
28 of emulated OLI bands (see Table 1). We find similarly high correlation coefficients ( $r =$   
29 0.94) to the regression method. Nevertheless, only the combination of blue and green bands  
30 had an RMSE below 1 m. This method appears to slightly overestimate lake depths. We  
31 | investigate the reasons for this with the [OLI](#) and WorldView data below.

1 Applying the empirical method using field data (see Table 1, Fig. 2) indicates that the more  
2 continuous bands of the ETM+ outperform the narrower (less spectrally auto-correlated)  
3 bands of the OLI when estimating lake depths. However, the addition of the coastal band  
4 should allow the OLI still to perform quite well ( $r > 0.92$ ,  $RMSE < 0.38$ ), in particular when  
5 paired with the green or panchromatic bands.

6 Our analysis shows that supraglacial lake depth retrievals using OLI are as good as or better  
7 than ETM+ retrievals. We identify the best methods for OLI (identified with asterisks in  
8 Table 1) based on the highest correlation coefficients and lowest RMSEs. We then apply  
9 these methods to OLI data and validate them with WorldView stereo DEMs.

## 10 4.2 2013 Northwest Greenland Results

11 In the northwest Greenland study area, we identified 694 lakes on 2 July 2013, with a total  
12 area of 27.2 km<sup>2</sup>, 1259 lakes totaling 43.7 km<sup>2</sup> on 18 July 2013, 955 lakes totaling 38.8 km<sup>2</sup>  
13 on 3 August 2013, and 274 lakes totaling 8.6 km<sup>2</sup> on 19 August 2013. We calculate lake  
14 depths with all previously discussed methods, as well as an average between the two best  
15 single-band depth estimates. Total lake volume in the study area increased in early July,  
16 stayed almost constant as lake growth areas moved higher in elevation over the following  
17 three weeks, and then decreased again toward the end of August as cooler conditions  
18 prevailed (see Fig. 3). While all methods show the same pattern of surface water storage, the  
19 total water volumes derived with the different methods differ by over a factor of 2.

20 [[Fig. 3]]

## 21 4.3 Comparison with DEMs

22 For both of our case study regions, northwest and southwest Greenland, we difference all  
23 overlapping areas of OLI-derived lake depths and WorldView-derived DEMs. The statistics  
24 of this comparison are shown in Fig. 4. As seen in the northwest Greenland case study, the  
25 results are divided into two groups. OLI-derived depths using band 3, bands 2 & 3, a ratio of  
26 bands 1 and 3, and a ratio of bands 1 and 8 all considerably overestimate lake depth relative to  
27 the DEMs. However, the physically based single band method for the red band (OLI Band 4)  
28 only slightly underestimates lake depth ( $-0.1 \pm 1.7$  m), while the panchromatic band (OLI  
29 Band 8) slightly overestimates lake depth ( $0.1 \pm 1.4$  m).

1 Combining these two best-performing bands, the resulting spectral and DEM-derived lake  
2 depths are in close agreement, showing a difference of  $0.0 \pm 1.6$  m. We infer that the optimal  
3 method for estimating supraglacial lake depth with ~~OLI~~ is to take an average of the physically  
4 based (see Eqn. 1) depths as derived from the red and panchromatic channels (bold in Table  
5 1). It is likely that the spread in depths is the result of a combination of factors including  
6 temporal offset between DEM and spectral data collection, image coregistration, and  
7 atmospheric effects, as well as uncertainties inherent in the lake depth retrievals. Despite  
8 meter scale uncertainties (1.6 m) at the pixel level, the mean lake depth derived from these  
9 methods agrees well.

10 [[Fig. 4]]

#### 11 4.4 2014 Sermeq Kujalleq Area Results

12 We apply the lake depth algorithm (i.e., average of single band depths from OLI red &  
13 panchromatic bands) to 34 ~~OLI images~~ from the summer of 2014 over the Sermeq Kujalleq  
14 area (see Figs. 1 & 5). The total meltwater storage in supraglacial lakes peaked near three  
15 cubic kilometers across the entire study area in mid-July 2014. There are many shallow lakes  
16 (0.3 to 1.5 m depth) and many lakes with depths of 2.5 to 4 m. Few lakes exceed 5.5 m depth  
17 (see Fig. 6a). The preponderance of shallow lake pixels reflects the fact that the observed  
18 lakes have low surface slopes at their edges.

19 [[Fig 5]]

20 If the water stored in supraglacial lakes in row 12 of path 008 in mid-July were spread across  
21 the whole 25,246 km<sup>2</sup> of ice in the scene, it would have an average depth of almost three  
22 centimeters. In other scenes, calculations provide average depths of 0.5 to 1.5 cm. Our  
23 maximum observed value is almost as high as the volume in supraglacial streams measured  
24 by Smith et al. (2015), reinforcing the potentially daily turnover of a well-connected surface  
25 system they observed. Indeed, Tedesco et al. (2012) observe bare ice melt rates next to  
26 supraglacial lakes in west Greenland of ~2.5-3 cm per day, similar to those observed by van  
27 den Broeke et al. (2011). This implies that lakes are storing on the order of one day's worth of  
28 melt (or less), indicating daily or subdaily residence times, depending on connectivity.

29 The Sermeq Kujalleq dataset ~~also~~ provides a time series that shows lake growth and drainage  
30 / freezing (see Fig. 5a). There are many factors that contribute to lake growth and drainage,  
31 including temperature, insolation, albedo, topography, and ice dynamics. These complex

1 drivers are related to the more easily quantified mean elevation and latitude of each scene. For  
2 example, isolating the coastal scenes shows the delayed onset of melt and earlier shutdown in  
3 the north compared to the south (see Fig. 5b).

4 To further refine our investigation of geographic factors associated with lake depth over the  
5 summer season, we examine single swaths of OLI imagery through time. Path 008 (in the  
6 WRS-2 reference scheme, Irons et al., 2012), which transects the lower Sermeq Kujalleq,  
7 shows a strong influence both of elevation and latitude in rates of lake growth and water  
8 storage (Fig. 5c). Isolating Path 006, on the other hand, conflates the effects of elevation and  
9 latitude on surface meltwater storage, but because we have more temporal coverage (see Fig.  
10 5d) we see the decline of total lake volume as summer progresses toward autumn. Again,  
11 higher latitude and elevation delay melt onset (i.e. Path 006, Row 012). For 006/013 and  
12 006/014, it is likely that the reduced ice sheet area within 006/014 is the explanation for the  
13 reduced meltwater volume. Rates of increase and decay of lake volume are similar for this  
14 pair.

15 The distribution of lake depths (by pixel) with elevation is shown in Fig. 6b. Lakes are  
16 distributed from ~300 m to ~2100 m elevation. Maximum lake depths occur at about 1200 m  
17 a.s.l. At lower elevations, lake depths recorded by our method vary significantly, likely due to  
18 rapid lake growth and drainage across a range of dates at lower elevations, versus the higher  
19 elevation maximum depths mostly derived from an OLI image on July 30 2014. From 1200 m  
20 to 2100 m, measured lake depths decline steadily with less variation. This likely reflects a  
21 combination of factors, including the variations in induced surface topography of the ice sheet  
22 as it flows over undulating bedrock (Lampkin and VanderBerg, 2011). At higher elevations,  
23 slow flow leads to low-amplitude ice surface topography thus shallower depressions, and  
24 there is also less available meltwater to fill ice-surface depressions. In addition, while lakes  
25 are less likely to variably fill and drain at higher elevations, there was also reduced imagery  
26 available from ~July 30 2014 onwards. Therefore, the more consistent maximum depths at  
27 higher elevations are a combination of incomplete temporal coverage and elevation. Further  
28 down, more melt and higher amplitude topography from faster ice flow facilitate lake  
29 formation. However, below 1200 m, increased ablation begins to reduce this topography. In  
30 addition, the volume of melt available will determine whether depressions are large enough to  
31 hold lakes or instead drain via connecting supraglacial channels. The melt volume and

Deleted: At higher elevations, slow flow leads to low-amplitude ice surface topography as well as less available meltwater.

1 therefore the relationship between lakes and channels will thus vary both seasonally and with  
2 elevation as well (Lampkin and VanderBerg, 2014).

3 [[Fig 6]]

## 4 5 Discussion

### 5 5.1 Retrieval Performance Factors

6 The depths returned by the empirical (band ratio) method considerably overestimate lake  
7 depths relative to the WorldView DEMs. The method is entirely dependent upon the  
8 calibration of the input parameters (i.e.,  $a$ ,  $b$ , and  $c$ ). The parameters used in this study are in  
9 turn based solely upon extrapolation from in situ measurements at a single lake. Therefore, it  
10 is possible that the lake used for calibration is not representative of lakes in our study region.  
11 Legleiter et al. (2014) note that the coefficients for the empirical method may be scale-  
12 dependent, and values calculated from field data may not be appropriate for the 30 m OLI  
13 pixels. Indeed, other work (Moussavi et al., in review) both calibrates and validates spectrally  
14 derived depths with WorldView DEMs to show that the band-ratio/empirical method and  
15 single-band/physically based method perform similarly well. The use of a ratio of coastal and  
16 green reflectances performed well for lake depth retrieval using WorldView-2 imagery  
17 (Legleiter et al., 2014). Therefore the band ratio method may, with better parameters, produce  
18 results consistent with the physically based single-band approaches.

19 The physically based depth retrievals show a large spread in total water volume returns.  
20 Physically based depth retrievals rely on accurate bottom albedos ( $A_d$ ) and water absorption  
21 coefficient ( $g$ ). While  $A_d$  is derived from the imagery,  $g$  is always calculated for each spectral  
22 band based on laboratory measurements and is therefore consistent across all OLI scenes.  
23 Comparison of laboratory-measured  $g$  with those derived from in situ data (see Table 1)  
24 shows that when the laboratory-measured  $g$  is higher than the that obtained from regressing in  
25 situ data, lake depths are overestimated and vice versa. For example, OLI Band 3 (green)  
26 shows a 70% difference in directly measured and regressed  $g$ , and it overestimates lake depths  
27 by a mean of  $2.4 \pm 2.1$  m relative to WorldView DEMs. By contrast, Band 4 (red) and Band 8  
28 (panchromatic) have very small differences between measured and regressed  $g$  (-0.06% and  
29 0.06%, respectively) and yield accurate lake depth estimates ( $-0.1 \pm 1.7$  m and  $0.1 \pm 1.4$  m,  
30 respectively) relative to WorldView DEMs.

1 Water absorption properties also vary with wavelength. For example, poor performance in  
2 blue and coastal bands is related to very low absorption. Red wavelengths attenuate relatively  
3 quickly in water, and this is described by a relatively high  $g$  ( $0.7507 \text{ m}^{-1}$ ) compared to green  
4 ( $0.1413 \text{ m}^{-1}$ ). This high  $g$  for red light makes it less sensitive to errors in  $g$  than green  
5 wavelengths. Lake depth estimates using a red channel are also less sensitive to  $A_d$  than with a  
6 green channel (Tedesco and Steiner, 2011), again due to the high absorption for longer  
7 wavelengths. Ultimately, as long as the sensor radiometry is able to measure the return from  
8 deep-water pixels, longer wavelengths (i.e., red) can return generally more accurate lake  
9 depths because they are less sensitive to the input parameters.

## 10 5.2 Revisiting Lake Depth Retrievals

11 To evaluate other studies in the literature and compare them with our results, we apply the  
12 same methods we use (i.e., lab-measured absorption/scattering parameters and appropriate  
13 spectral response functions) to calculate  $g$ 's for ETM+ bands (see Table 1). Tedesco and  
14 Steiner (2011) studied the accuracy of ETM+'s green band for lake depth estimation. They  
15 tested different multipliers of the diffuse attenuation coefficient for downwelling light to get  
16 the water absorption coefficient  $g$ . They showed that for ETM+'s green band, sonar and  
17 spectral depths correlated better when a larger multiplier was used. This is broadly consistent  
18 with the 70% offset between observed and theoretical values that we observe (Table 1). They  
19 also find that this offset "cannot be easily explained, aside from a possible chlorophyll  
20 concentration in the water, currently considered to be unlikely." Morriss et al. (2013) used  
21 ETM+'s red band and extracted a higher value of  $g$  ( $0.86 \text{ m}^{-1}$ ); this is very close to the  
22 regressed value we observe of  $0.83 \text{ m}^{-1}$  (see Table 1), and so we expect their depth estimates  
23 to be slightly overestimated.

Deleted: Landsat 7

24 Banwell et al. (2014) and Arnold et al. (2014) also used ETM+'s green band with a  $g$  of  
25  $0.1954 \text{ m}^{-1}$ , ~40% percent higher than our regressed value of  $0.14 \text{ m}^{-1}$ , leading to depths  
26 overestimated by ~30%. Because the comparisons of Greenland and Antarctic lakes (Banwell  
27 et al., 2014) are based on relative depths, their conclusions are likely still valid. Arnold et al.  
28 (2014) concluded that their model under-predicted water depths, which could in reality mean  
29 that their model is behaving correctly but their validation data (i.e., ETM+ lake depths) were  
30 biased.

1 Using the same process as for Landsat sensors, we calculated  $g_s$  for ASTER, MODIS, and  
2 WorldView-2 bands (see Table S1). Sneed and Hamilton (2007, 2011) used ASTER's green  
3 band for lake depth estimation ( $g = 0.1180 \text{ m}^{-1}$ ). This is ~20% smaller than the regressed  
4 value of  $0.15 \text{ m}^{-1}$  (see Table S1). They will therefore have likely underestimated lake depth  
5 (Sneed and Hamilton, 2007).

6 For all three studies, the regressed  $g_s$  are much closer to the updated lab-based  $g_s$  (see Sect.  
7 2.1 & Supplementary Material) than those used in the studies. Adoption of the new  $g_s$   
8 presented here in Tables 1 and S1 would therefore likely lead to improved lake depth  
9 estimates.

### 10 5.3 Sensitivity Analysis

11 For all sensors, wavelengths, and input parameters, an important consideration for  
12 reflectance-derived lake depth is the atmospheric correction used to prepare the multispectral  
13 imagery. All imagery is processed to TOA reflectance, which means that there is some  
14 extraneous path radiance remnant in the data. Therefore, TOA values will slightly  
15 overestimate the true reflectance. This offset will not be the same between bands, and will  
16 influence the retrieved lake depths as discussed below.

17 The single band physically based model requires that the reflectance of optically deep water  
18 be derived for each scene separately. Effectively, this shifts the exponential decay curve of  
19 light in lake water but does not change its shape. Therefore, as long as path radiance is  
20 assumed to be homogeneous across the 185-km wide OLI scene, TOA reflectance is sufficient  
21 for lake depth estimation. To test this assumption, the MODTRAN radiative transfer model  
22 (Berk et al., 2005) was used to simulate path radiance on a day for which OLI data were used  
23 in northwest Greenland (18 July 2013) to investigate variations associated with variable water  
24 vapor and ozone across a Landsat scene. According to MODIS retrievals (accurate to 30 DU;  
25 Borbas et al., 2011), ozone variability within a Landsat scene is on the order of approximately  
26  $\pm 50 \text{ DU}$ , which translates to a path radiance of  $\pm 1.6\%$  in the red channel. For lake depth, this  
27 can propagate to a ~20% error in lake depth. Much of this error appears largely random for a  
28 given point in time and space. Thus, while it decreases confidence in individual lake depth  
29 retrievals, averaged water volume retrieval should not be biased. For water vapor there was a  
30 0.3% change in path radiance between the minimum and maximum Landsat scene values,

1 making it a small contributor to overall error. Between days, however, path radiance effects  
2 due to water vapor may vary by an order of magnitude more.  
3 For the multiple band methods, the differential change in path radiance has larger effects.  
4 Sensitivity tests showed that a 3% change in path radiance for one or both bands changed  
5 water volumes on the order of 10-30%. Therefore, a more rigorous atmospheric correction is  
6 necessary in order to apply multi-band lake depth algorithms. Still, for the study here, because  
7 validation is conducted across 12 non-consecutive days in both spring and autumn, we do not  
8 expect atmospheric conditions to bias our conclusions.

9 There are additional limitations to our method. As discussed above, OLI lake depth estimates  
10 (average single-band estimates from red and panchromatic bands) are robust for regional  
11 averages but not single pixels. In addition, the threshold used to identify lake extent may need  
12 to be adjusted for different regions and scenes (e.g. Banwell et al., 2014; Box and Ski, 2007).  
13 Lake depth retrievals are also sensitive to variations in ice albedo, as well as to the presence  
14 of ice lids on the surface of supraglacial lakes, which can be common both in early and late  
15 summer. Cloud cover and Landsat's 16-day revisit time also limit the conclusions that can be  
16 drawn from OLI lake depths. Many studies have used daily MODIS data to identify and track  
17 supraglacial lakes (e.g. Liang et al., 2012; Selmes et al., 2011; Sundal et al., 2011). Fusing the  
18 higher temporal resolution of MODIS (or additional sensors such as ESA's upcoming  
19 Sentinel-2) and higher spatial resolution of OLI, along with more in situ calibration and  
20 validation data, should lead to unique insights to supraglacial water storage.

## 21 **6 Conclusion**

22 Examination of the evolution of water storage on the surface of ice sheets and glaciers is  
23 important for understanding mass balance, dynamics, and heat transport throughout the ice  
24 mass. In this study, in situ data were used to test the capability of Landsat 8's **Operational**  
25 **Land Imager** to estimate supraglacial lake depth. Promising methods were applied to two sets  
26 of OLI observations. Patterns of water storage were similar from the two methods, but a  
27 factor of two difference was calculated for the total water volume. WorldView DEMs were  
28 used to assess which of the methods was most accurate. The best method identified for OLI  
29 was an average of the depth derived from single-band physically-based retrievals of Band 4  
30 (red) and Band 8 (panchromatic); the mean difference between spectrally-derived and DEM-  
31 derived lake depths is only  $0.0 \pm 1.6$  m, showing no bias but some spread. Therefore, this  
32 method is recommended for future lake depth retrievals with OLI, especially for regional

**Moved up [1]:** Both supraglacial lakes and channels can contribute significantly to regional water storage and transport (Smith et al., 2015). If the water stored in supraglacial lakes in row 12 of path 008 in mid-July were spread across the whole 25,246 km<sup>2</sup> of ice in the scene, it would have an average depth of almost three centimeters. In other scenes, calculations provide average depths of 0.5 to 1.5 cm. Our maximum observed value is almost as high as the volume in supraglacial streams measured by Smith et al. (2015), reinforcing the potentially daily turnover of a well-connected surface system they observed. Indeed, Tedesco et al. (2012) observe bare ice melt rates next to supraglacial lakes in west Greenland of ~2.5-3 cm per day, similar to those observed by van den Broeke et al. (2011). This implies that lakes are storing on the order of one day's worth of melt (or less), indicating daily or subdaily residence times, depending on connectivity. .

1 studies. This is the first time supraglacial lake depths have been validated across multiple  
2 dates and regions.

3 Discrepancies between spectrally- and DEM-derived depths appear to be explained by  
4 differences between lab-measured and in situ-derived water absorption coefficients ( $g$ ). The  
5 success of other sensors and bands in deriving supraglacial lake depth can thus be inferred  
6 from these  $g$ 's. With this insight, multispectral lake depth estimates in the literature were  
7 revisited. Lake extent studies can now be expanded to include lake volume with higher  
8 confidence. Updated  $g$ 's are provided (see Tables 1 and S1), but further in situ data collection  
9 and satellite-based studies are needed to build more robust methods.

10 The recommended depth retrieval method was applied to all available OLI imagery for  
11 summer 2014 for the Sermeq Kujalleq (Jakobshavn) region of west Greenland. Seasonal and  
12 regional trends in lake depth (deepening and then shallowing), evolution (proceeding  
13 inland/up-glacier and northwards through the summer), and distribution (~300 m to ~2100 m  
14 a.s.l.) were observed. At most, lakes contain a similar magnitude of water to supraglacial  
15 streams, but this may not be true for other parts of Greenland. Both elevation (and relatedly,  
16 accumulation / melt forcing) and surface topography play a role in lake formation and extent,  
17 behavior that we expect to be modified but observable in other regions. Further work moving  
18 forward will need to contextualize Landsat data with other remote sensing imagery,  
19 fieldwork, and model outputs.

1 Table 1. Laboratory-based and in situ-derived water absorption coefficients for lake depth  
 2 estimation using the physically based method ( $g$ , see Eqn. 1) and empirical method ( $a$ ,  $b$ , and  
 3  $c$ , see Eqns. 5-6). Regression statistics (correlation coefficient and root mean squared error)  
 4 for lake depth estimates using field spectra convolved to emulate multispectral bands are also  
 5 included. Asterisks indicate the methods applied to OLI data in this paper. Bold text indicates  
 6 recommended bands for lake depth estimation with OLI. See Table S1 for results from other  
 7 multispectral sensors.

Figure 1. Regional map showing the two study regions for lake depth estimation using OLI imagery. The northwest Greenland study region is identified with a single box indicating a subscene area. The Sermeq Kujalleq study region shows WRS-2 path/row outlines for Landsat scenes color-coded and dashed to indicate the mean latitude and average elevation of ice within the scenes (see Sect. 4.4 and Table S2). The background is elevation from the Greenland Ice Mapping Project (GIMP) DEM (Howat et al., 2014, 2015).

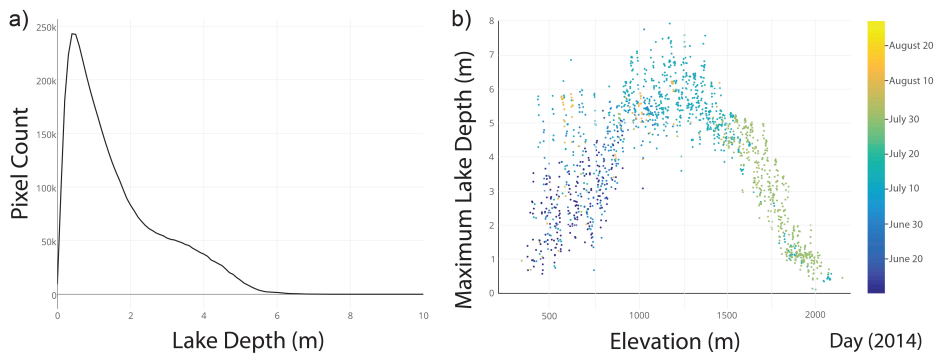

Figure 4. Statistics for the difference in supraglacial lake depth from physically based and empirical methods derived from OLI imagery and WorldView DEMs, including mean/standard deviation (solid lines) and median/quartiles (dotted lines). An average of the Band 4 and Band 8 methods is used for our mapping (Figures 5 and 6). The method showing the least bias and lowest errors is an average of Band 4 (red) and Band 8 (panchromatic) single band physically based retrievals, with a mean offset of  $0.0 \pm 1.6$  m (as indicated by the bar at the bottom of the diagram). Discrepancies in lake depth estimation for physically based retrievals can be traced to differences between lab-measured and in-situ-regressed water absorption coefficients (see Table 1).

Figure 5. Total water stored in supraglacial lakes over the 2014 summer using single Landsat 8 scenes (as indicated by WRS-2 path/row annotations) covering the Sermeq Kujalleq region (see Fig. 1, Table S1). All scenes are shown together in (a). (b) shows only the low elevation, coastal scenes, demonstrating delayed lake formation at higher latitudes. (c) shows both elevation and latitude effects in driving supraglacial water storage for scenes in WRS-2 path 8. (d) shows latitude and elevation effects for scenes in WRS-2 path 6. All sub-figures are on the same grid as part (a).
