

Interactive comment on “Active Layer Thickness Estimation from X-Band SAR Backscatter Intensity” by Barbara Widhalm et al.

Anonymous Referee #1

Received and published: 23 September 2016

Although all three reviewers used different words, I think we all say essentially the same thing: the authors need to create a link between those vegetation characteristics (or land cover classes) that drive both x-band backscatter and ALT dynamics. Overlapping vegetation characteristics that influence both backscatter and ALT would simultaneously provide both a motivation for the study and an explanation of the results. The authors find that backscatter correlates with ALT, at least for $ALT > 70$ cm, clearly indicating a relationship. The missing piece of the manuscript and the significant scientific advance is explicitly identifying what vegetation characteristics drive this relationship.
