

Supplementary information

S1: Density profiles of the six firn cores from Union Glacier (UG). Density profiles of cores BAL-1 and PASO-1 were obtained by X-ray microfocus tomography and are at $< 1\text{ mm}$ resolution. The running mean is shown in red. The window size for calculating the running mean was chosen to be 1700 points for BAL-1 and 1250 points for PASO-1 as these values correspond to a period of approximately half a year within the respective core record. For each core the linear trend of increasing density with depth due to firn compaction and the approximate depth of the snow-firn-density boundary (0.55 g/cm^3 ; grey bar) are indicated. Note that for core DOTT-1 the snow-firn-density boundary is not reached within the drill depth and therefore its location was determined by linear extrapolation at the lower end of the core.

S2: Profiles of the stable water isotope composition ($\delta^{18}\text{O}$) of the six firn cores from UG with respect to depth.

S3: Non-standardized annual mean stable oxygen isotope composition of the six firn cores from UG for the period covered by the respective core. Sen slopes (s) and p-values are given for each core.

S4: Results of cross-correlation analysis for accumulation rates and mean annual stable water isotope composition of the six firn cores from UG. Prominent correlations are marked bold and if statistically significant (p-value < 0.01, $\alpha = 0.05$) in red and bold.

S5: Non-standardized annual mean d excess of the six firn cores from UG for the period covered by the respective core. Sen slopes (s) and p-values are given for each core.

S6: Non-standardized seasonal means of near-surface air temperature (derived from the AWS composite record) and firm core $\delta^{18}\text{O}$ in the UG region for the period 2010–2015.
