15 ABSRACT: Ice and snowmelt feed the Indus and Amu Darya rivers in western High Mountain 16 Asia, yet there are limited in situ measurements of these resources. Previous work in the region 17 has shown promise using snow water equivalent (SWE) reconstruction, which requires no in situ 18 measurements, but validation has been a problem. However, recently we were provided with daily 19 manual snow depth measurements from Afghanistan, Tajikistan, and Pakistan by the Aga Khan 20 Agency for Habitat (AKAH). To validate SWE reconstruction, at each station, accumulated 21 precipitation and SWE were derived from snow depth using the numerical snow cover model 22 SNOWPACK. High-resolution (500 m) reconstructed SWE estimates from the ParBal model were 23 then compared to the modeled SWE at the stations. The Alpine3D model was then used to create 24 spatial estimates at 25 km resolution to compare with estimates from other snow models. 25 Additionally, the coupled SNOWPACK and Alpine3D system has the advantage of simulating 26 snow profiles, which provide stability information. The median number of critical layers and 27 percentage of faceted layers across all of the pixels containing the AKAH stations was computed. 28 For SWE at the point scale, the reconstructed estimates showed a bias of -42 mm (-19%) at peak 29 SWE. For the coarser spatial SWE estimates, the various models showed a wide range, with 30 reconstruction being on the lower end. A heavily faceted snowpack was observed in both years, 31 but 2018, a dry year, according to most of the models, showed more critical layers that persisted 32 for a longer period.

33 1 INTRODUCTION

- 34 There are many parts of the world where little is known about the snowpack. This lack of
- 35 knowledge presents a challenge for water managers and for avalanche forecasters. Afghanistan is
- 36 particularly austere in this respect, as there have been no snow measurements available since the
- early 1980s. This lack of information about the snowpack potentially creates a humanitarian crisis,
- as snowmelt fed streams run dry in the fall without warning (USAID, 2008). Accurate historical
- 39 estimates of basin-wide snow water equivalent (SWE) are crucial for creating a baseline of
- 40 climatological conditions, which can then aid in predicting today's SWE. For example, SWE
- 41 climatology is the most important predictor in machine learning statistical models for this region
- 42 (Bair et al., 2018a).
- To improve our knowledge about the snowpack in these areas, we have developed an approach
- 44 that requires no in situ measurements. Using satellite-based estimates of the fractional snow-
- 45 covered area (fSCA) and downscaled forcings in an energy balance model, we build up the
- snowpack in reverse, from melt out to its peak, using a technique called SWE reconstruction
- 47 (Martinec and Rango, 1981). This technique has been shown to accurately estimate SWE in
- 48 mountain ranges across the world, including: the Sierra Nevada USA (Rittger et al., 2016;Bair et
- al., 2016); the Rocky Mountains USA (Jepsen et al., 2012; Molotch, 2009); and the Andes of South
- America (Cornwell et al., 2016)—all areas with relatively abundant independent ground validation
- 51 measurements. For the so called Third Pole of High Mountain Asia, and especially the
- 52 northwestern parts of this region, e.g. Afghanistan, Tajikistan, and Pakistan, ground-based
- validation is challenging.

54

2 AGA KHAN AGENCY FOR HABITAT (AKAH) STATIONS

- In 2017, we received daily manual snow depth and other meteorological measurements from
- nearly 100 stations (Figure 1) in an operational avalanche network (Chabot and Kaba, 2016). These
- 57 stations are funded by the Aga Khan Agency for Habitat (AKAH) and are the first snowpack
- measurements available, at least that we are aware of, in Afghanistan in nearly 40 years. Hence,
- 59 we refer to the region as the AKAH study region and the weather stations as the AKAH stations.
- The AKAH stations contain manual daily snow depth (also called height of snow), height of new
- 61 (24-hr) snow, daily high and low air temperature, instantaneous wind speed/direction, rainfall, and
- (2+ iii) show, dury high and low an temperature, instantaneous which spectral retirent, raintan, and
- some text fields on weather and avalanche conditions. For mountainous areas, precipitation is the
- most uncertain term in the water balance (Milly and Dunne, 2002; Adam et al., 2006) because it
- exhibits high spatial variability and is difficult to measure with traditional gauges. Measuring snow
- on the ground has many advantages compared to using precipitation gauges, which suffer from
- 66 undercatch, especially in the windy and treeless areas (Lehning et al., 2002a; Kochendorfer et al.,
- 67 2017; Goodison et al., 1998) typical of this part of the world. Likewise, a strength of the SWE
- 68 reconstruction technique is that it does not depend on precipitation measurements to build the
- 69 snowpack.
- Additionally, many of the AKAH stations are at high elevation, with 64 stations above 2500 m
- and 17 stations above 3000 m. Unfortunately, most of these stations are located in deep valleys,
- where the villages are, rather than on the mountains above and the daily resolution is too coarse to
- use in a snow model without temporal interpolation. Additionally, many of the stations are near
- 74 glacierized areas which complicates spatially interpolated snow estimates, as some of the snow is
- on top of ice. The area covered by glaciers in Figure 1 is 7.8%.

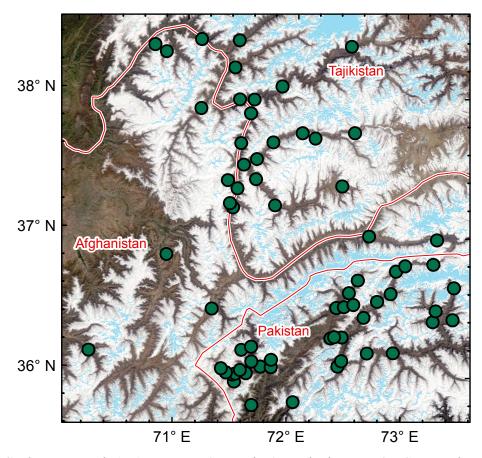

Figure 1 Study region with AKAH stations (green dots) overlaid on a MODIS true color image from 13 April 2018. Also shown are the country boundaries (red) and glacierized areas (light blue) from the Global Land Ice Measurement from Space dataset (Raup et al., 2007). All of the stations in Afghanistan and Tajikistan are in areas that eventually flow into the Amu Darya River. All of the stations in Pakistan are in areas that eventually flow into the Indus River.

Although there have been a large number of studies examining the glaciers of High Mountain Asia, there are fewer studies examining snowfall in High Mountain Asia, which is odd since hydrologically in this region, snow on land melt provides the vast majority of runoff compared to snow on ice and melting glacier ice (Armstrong et al., 2018). Many of these studies are focused on the region to the east of the AKAH study area shown in Figure 1. To our knowledge, there have been no studies on snowpack stratigraphy in the AKAH study area and we were unable to obtain any snow pit measurements from this area.

3 LITERATURE REVIEW

A few studies have specifically examined snowfall in larger regions that include some of the AKAH stations, mostly for stations in the southern basins that flow into the Indus River; that is all of the stations in Pakistan. The rest of the stations in Afghanistan and Tajikistan are in basins that flow into the Amu Darya River. The most comparable study (Shakoor and Ejaz, 2019) examines the Passu catchment in the Hunza River Basin, to the east of Figure 1. As in this study (Section 5.1), Shakoor and Ejaz (2019) also use the SNOWPACK and Alpine3D models. Model parameters were calibrated using a single weather station, Urdukas at 3926 m elevation near the Baltoro glacier

92 (Ev-K2-CNR, 2014), with one year of precipitation measurements, using snow depth for 93 validation. The authors report overestimation of the measured snow depth at the calibration station, 94 even after questionable adjustments to the snow albedo and other model parameters. For example, 95 the snow and ice albedo is given as 0.20 to 0.30 (Table 3, Shakoor and Ejaz, 2019), which would make it 0.10 to 0.20 lower than some of the lowest measured broadband albedo values for dirty 96 97 snow (Bair et al., 2019; Skiles and Painter, 2016). They attribute the overestimation to problems 98 with the precipitation measurements, common for high elevation stations. One problem with the 99 Urdukas station in particular is that the tipping bucket precipitation gauge is unheated, making it 100 unusable for measuring solid precipitation. Temperatures at this station were well below freezing 101 for the winter and most of the spring, which explains why no precipitation was recorded from 102 January until sometime in March during 2012, the calibration year.

103 Viste and Sorteberg (2015) study several gridded precipitation products throughout High Mountain 104 Asia, including the Indus River Basin. They report that while total precipitation was similar across 105 the products-including MERRA (Rienecker et al., 2011), APHRODITE (Yatagai et al., 2012), 106 TRMM (Huffman et al., 2007), and CRU (Harris et al., 2014)-the total snowfall varied by a factor of 2 to 4. Smith and Bookhagen (2018) used 24 years (1987 to 2009) of satellite-based passive 107 108 microwave SWE estimates to examine trends throughout High Mountain Asia, including the Amu 109 Darya and Indus Basins. Their SWE estimates show most 25 km pixels in this region in the 50-110 100 mm range for December through February, with a few over 100 mm in the Amu Darya (i.e. 111 all the AKAH stations in Afghanistan and Tajikistan) and none over 100 mm in the Indus (i.e. all 112 the AKAH stations in Pakistan), likely too low by an order of magnitude for some pixels given our previous reconstructed SWE values and limited climate measurements in Afghanistan (Bair et al., 113 114 2018a).

For the AKAH stations in Tajikistan, the most comprehensive snow measurements come from Soviet snow surveys (mostly depth, but with some SWE and density measurements) that have been digitized (Bedford and Tsarev, 2001). Most of these measurements begin in the late 1950s and end around the fall of the Soviet Union, in either 1990 or 1992, making them useful for climatological studies, but not for validation of modern satellite-based estimates.

The sole source of snow measurements in Afghanistan that were accessible to us was a table of outdated WMO monthly climatological data from Kabul (el. 1791 m) and North Salang (el. 3366 m), showing the maximum monthly snow depth and the mean number of days with snow (Table 1 in Bair et al., 2018a). Again, these measurements are not useful to validate more modern snow estimates.

125 There have been many other studies that have attempted to estimate basin-wide precipitation (including snowfall) for larger areas that include the AKAH region, especially in the Indus. Several 126 127 climate studies of the Indus have focused on using lower elevation precipitation gauges, which are 128 then used to spatially interpolate basin-wide precipitation. Dahri et al. (2016) and Dahri et al. 129 (2018) have assembled perhaps the largest collection of climatological measurements covering the 130 AKAH region, mostly based on gauge measurements, as part of a study on the hydrometeorology of the Indus Basin. Using undercatch corrections based on wind, often from reanalysis, they 131 132 increased precipitation estimates by 21% on average throughout the Indus Basin (Dahri et al., 133 2018). For example, in the Gilgit sub-basin, they find an unadjusted precipitation estimate of 582 134 mm/year, adjusted to 787 mm/year, a 35% increase. Although some of the measurements are taken 135 from publicly available sources, as with most publications for this region, the comprehensive data

used are not publicly accessible.

- 137 A similar but less sophisticated approach was used by Lutz et al. (2014), who used a constant
- increase of 17% across the APHRODITE precipitation dataset which covers all of High Mountain
- Asia. Immerzeel et al. (2015) used glacier mass balance estimates with streamflow measurements
- 140 as validation to show that high-altitude precipitation in the upper Indus Basin is 2 to $10 \times$ what is
- shown using gridded precipitation products like APHRODITE. Bookhagen and Burbank (2010)
- estimate that snowmelt contributes 66% of annual discharge to the Indus, and averages 424 mm
- across the basin.
- In summary, quite a few studies have produced varying precipitation and snowfall estimates for
- the AKAH region, with no recent in situ snow measurements from Afghanistan or Tajikistan.

146 4 PREVIOUS WORK WITH AKAH SNOW MEASUREMENTS

- Our previous work (Bair et al., 2018a) used a simple density model (Sturm et al., 2010) based on
- snow climatology (Sturm et al., 1995) and day of year to model SWE from the manual snow depth
- measurements. The density model itself has -12 to 26% bias in predicting SWE. When taking into
- account geolocational uncertainty of the reconstructed SWE estimates and uncertainty in the
- density model, errors are on the order of 11-13% Mean Absolute Error (MAE) and -2 to 4% bias,
- depending on the date. However, we only examined one year of the AKAH station data (2017)
- and the high uncertainty in the density model itself begs a more sophisticated approach.
- 154 From recent work (Bair et al., 2018b), we have shown that the SNOWPACK (Lehning et al.,
- 2002b; Lehning et al., 2002a; Bartelt and Lehning, 2002) model is capable of accurate SWE
- prediction when supplied only with snow depth for precipitation, as well as the other requisite
- forcings (i.e. radiation, snow albedo, temperatures, and wind speed). Over a 5-year period using
- hourly in situ measured energy balance forcings and a snow pillow for validation at a high
- elevation site in the western US, the numerical snow cover model SNOWPACK modeled SWE
- showed a bias of -17 mm or 1% (Bair et al., 2018b). Likewise, the success of the Airborne Snow
- Observatory (Painter et al., 2016) has demonstrated that given accurate snow depth measurements,
- 162 SWE can be well modeled.

163 5 METHODS

- Our modeling approach consisted of: a) downscaling forcings in ParBal and reconstructing SWE;
- b) combining the downscaled forcings for each AKAH station with temporally interpolated manual
- snow measurements; c) running SNOWPACK for each of the AKAH stations with the downscaled
- and interpolated measurements from a) and b); and d) running Alpine3D using the output from
- 168 SNOWPACK, notably the hourly precipitation. In addition to predicting SWE, the
- SNOWPACK/Alpine3D coupled model also predicts stratigraphic parameters useful for avalanche
- forecasting, thereby giving us an idea of the layering and stability in this region. For comparison,
- we also ran the NOAH-MP land surface model over the region with widely-used forcings. We also
- compared spatial estimates of SWE from GLDAS-2. Methods are summarized in Table 1 and
- explained below, with more detail provided in Appendix A.

174 5.1 SNOWPACK and Alpine3D

- 175 SNOWPACK and Alpine3D are freely available (https://models.slf.ch) point and spatially
- distributed snow models, courtesy of the Swiss Snow and Avalanche Research Institute SLF.

SNOWPACK is the older of the two and uses finite elements to model all of the layers in a snowpack at a point.

| | | | | | 1 |
|----------|----------------------|------------------------|-------------|---|---|
| Model | Point comparison? | Spatial comparison? | Version | Forcings | Output |
| ParBal | | √ | 1.0 | CERES 4a (radiation); GLDAS-2 (meteorological); MODSCAG/MODDRFS (snow surface properties) | Daily reconstructed SWE at 500 m; hourly downscaled forcings at 500 m, both for entire AKAH study area |
| SNOWPACK | $\sqrt{}$ | | 3.5 | AKAH station snow measurements; downscaled forcings from ParBal | Hourly SWE, precipitation, and other forcings for each AKAH station |
| Alpine3D | | $\sqrt{}$ | 3.1 | AKAH station output from SNOWPACK | Daily SWE at 25 km for entire AKAH study area |
| NOAH MP | | $\sqrt{}$ | 3.6 | MERRA-2 | Daily SWE at 25 km for entire AKAH study area |
| GLDAS | | $\sqrt{}$ | NOAH 2.1 | various | Daily SWE at 25 km for entire AKAH study area |

Table 1 Summary of models used. See Section 5 and Appendix A for an explanation of acronyms and further details.

SNOWPACK has shown promising results in both operational (e.g. Lehning et al., 1999; Nishimura et al., 2005) and research applications (e.g. Bellaire et al., 2011; Hirashima et al., 2010). Previous results with SNOWPACK (Bair et al., 2018b) show high model sensitivity to precipitation, but only a 1% error in modeled SWE when using snow depth only (not total precipitation) as a forcing. Thus, given reliable snow depth measurements at each AKAH station (see Section 5.5), modeled SWE during the accumulation season is treated as having negligible uncertainty. During the ablation season (after peak SWE), uncertainty is higher. Unlike during snow accumulation events, SNOWPACK does not force its modeled snow ablation to match the measured snow depth decreases. Uncertainty in SWE during the ablation season is then largely dependent on radiative forcings (Marks and Dozier, 1992) and the broadband snow albedo (Bair et al., 2019). Here, 5% uncertainty is used, based on the MAE from SWE reconstructions using the same remotely-sensed forcings at a continental sub-alpine site (Bair et al., 2019). In the same study, a small (3%) bias in SWE was also found, but this is likely due to shortcomings with the reconstruction method and not applicable to SWE modeled with SNOWPACK. Thus, the small

- bias was ignored. We acknowledge that these uncertainty estimates are themselves uncertain, e.g.
- the reanalysis forcings could be especially poor for this region compared to those available in the
- 197 western US.
- 198 Alpine3D (Lehning et al., 2006) is essentially a spatially-distributed version of SNOWPACK with
- a number of additional modules including: terrain-based radiation modeling, blowing snow, and
- 200 hydrologic modeling. Integral to Alpine3D is SNOWPACK, which is run for each pixel, as well
- as the MeteoIO library (Bavay and Egger, 2014), which provides a large number of temporal and
- spatial interpolation functions that can be used on forcings for Alpine3D and SNOWPACK.

203 5.2 The Parallel Energy Balance Model

- The Parallel Energy Balance Model (ParBal) was created at UC-Santa Barbara and designed for
- 205 reconstruction of SWE. It is also publicly available
- 206 (https://github.com/edwardbair/ParBal/releases/tag/v1.0). Currently, ParBal is designed to use:
- downscaled temperature, pressure, and humidity from version 2 of the Global or National Land
- Data Assimilation System (GLDAS-2/NLDAS-2, Xia et al., 2012;Rodell et al., 2004); shortwave
- and longwave radiation from edition 4a of the Clouds and the Earth's Radiant Energy System
- 210 (CERES, Rutan et al., 2015) SYN product; and time-spaced smoothed (Dozier et al., 2008; Rittger
- et al., in press) snow surface properties from MODIS Snow Covered Area and Grain Size
- 211 ct al., iii piess) show surface properties from MODIS show Covered Area and Orani Size
- 212 (MODSCAG, Painter et al., 2009) and MODIS Dust and Radiative Forcing in Snow (MODDRFS,
- Painter et al., 2012). ParBal is run hourly at 500 m spatial resolution and forcings are adjusted for
- 214 terrain and elevation. The main output is the residual energy balance term, which is assumed to go
- into melt when positive during the ablation phase after cold content is overcome (Jepsen et al.,
- 216 2012). This residual melt term is then summed in reverse during periods of contiguous snow cover
- and multiplied by the fSCA to spread the snow spatially. The errors in SWE from ParBal are
- 218 mostly from fSCA and the radiative forcings. Errors and details on ParBal are covered extensively
- in Bair et al. (2016) and Rittger et al. (2016). In the supplement for Bair et al. (2018a), the errors
- arising from using GLDAS-2 and CERES 4a (available worldwide but at coarser spatial resolution)
- 221 vs. NLDAS-2 are specifically evaluated. Using three years of basin-wide SWE estimated by the
- 222 Airborne Snow Observatory in the upper Tuolumne Basin, California USA, the MAE for ParBal
- 223 was 25 mm or 26% (Bair et al., 2018a).

224 5.3 Global Data Assimilation System 2 (GLDAS-2)

- For comparison, we also include the SWE estimates from GLDAS-2 (Noah). SWE from GLDAS-
- 226 2 has been shown to be comparable to estimates from other reanalysis datasets, but negatively
- biased by about 60% in comparison to higher spatial datasets with assimilation from snow station
- measurements (Broxton et al., 2016).

229 5.4 NOAH Multi-Parameterization (MP)

- The NOAH-MP v3.6 (Niu et al., 2011; Ek et al., 2003) land surface model, forced using MERRA-
- 231 2 (Gelaro et al., 2017), was used to simulate the hydrologic cycle over the study area and provide
- SWE estimates for comparison with ParBal and the Alpine3D output. NOAH-MP was selected
- due to its detailed representation of the snowpack relative to other land surface models. The model
- subdivides the snowpack into up to three layers with associated liquid water storage and
- 235 melt/refreeze capability (Yang and Niu, 2003; Niu and Yang, 2004). It incorporates the exchange

- 236 of heat and moisture through the snowpack between the land surface and the atmosphere. In a
- 237 model intercomparison study using a 2 km spatial resolution regional climate model for forcings,
- Chen et al. (2014) show that NOAH-MP modeled peak SWE at SNOTEL sites in Colorado, USA 238
- 239 with a -7% bias.
- 240 5.5 Use of AKAH station measurements
- 241 We modeled daily SWE at the AKAH stations during the 2017 and 2018 water years (WY)
- 242 primarily using the manually measured height of snow (HS), also called snow depth, combined
- 243 with our downscaled energy balance parameters (for downscaling methodology see Rittger et al.,
- 2016; Bair et al., 2016; Bair et al., 2018a). To our knowledge, no quality control was performed on 244
- 245 the AKAH station measurements before we received them. We choose the manual HS and new
- 246 (24-hr) snow (HN) as the only variables to use from the AKAH stations. The HS appeared to be
- 247 the most reliably measured, as that only requires reading a value from a master snow depth stake.
- 248 Apart from spurious drops or missing values (see below), the HS measurement appeared consistent
- 249 and believable at most of the stations, implying an accurate snow depth record. The HN was used
- 250 to correct a data entry problem in 2017 that we discuss below. The reliability of the other
- 251 measurements (instantaneous wind speed/direction, maximum/minimum temperature, and
- 252 rainfall) was questionable. For example, we were not provided with sensor or measurement
- 253 metadata, e.g. sensor make/model, measurement height, and whether or not the temperature sensor 254
- was shielded from shortwave radiation. These other measurements taken daily were also of limited
- 255 value for interpolation to hourly values (see item 3 below). Thus, these other measurements were
- 256 not used.
- 257 The AKAH dataset had a number of shortcomings that we list here along with how we addressed
- 258
- 259 1) Some of the stations recorded no snow at all, especially in the dry 2018 year, or had obvious
- 260 problems, such as weeks of missing measurements, so they were excluded. For 2017, 52 (54%)
- 261 of stations were used. For 2018, 41 (46%) stations were used.
- 262 2) There were spurious drops in the HS measurements. The drops were clearly cases of missing 263 values being filled with zeros. These measurements were manually flagged and converted to
- 264 null values for interpolation, see below.
- 265 3) The daily measurements had to be interpolated to hourly values. For the most part we used
- 266 linear interpolation, although this is not ideal during snow accumulation since it's almost never the case that snowfall is uniform over a 24-hr period. This is a problem that affects the accuracy 267
- of snow settlement estimated by SNOWPACK. There were two cases where other interpolation 268
- methods were used. If there were several days of missing values, we used a nearest neighbor 269
- 270 interpolation to fill in the missing daily values, followed by a linear interpolation from daily to
- 271 hourly measurements such that we assumed all the new snow fell in a 24-hr period. The other
- 272 case was for days where the linear interpolation would yield a value below the minimum
- 273 threshold hard coded into SNOWPACK (0.5cm/hr) for the first accumulating snowfall on bare
- 274 ground. In this case, a previous neighbor interpolation was used in such a way that the entire
- 275 snowfall occurred in the last hr prior to the next day's measurement.
- 276 4) We found the AKAH stations suitable for snow on the ground measurements, but not for
- 277 rainfall or total (solid+liquid) precipitation. This was only an issue for the Alpine3D snow
- modeling, as snow measurements were being extrapolated to higher elevations than the AKAH 278

- stations (Section 6.2), thus at these higher elevations, snow accumulated earlier and melted later than at the lower AKAH stations.
- 281 Given the near total lack of canopy cover in the region, we suspected substantial undercatch from
- rain gauges. Using the wind speed, an undercatch correction would have been possible given more
- information on the gauges (e.g. orifice opening diameter and whether or not a shield was present),
- 284 however this instrument metadata was not available to us. Likewise, we did not know if the gauges
- were heated or not.
- Further, the time period for recording measurements from the stations was not consistent. In WY
- 287 2017, measurements began being reported on 10 November 2016 and were reported until 24
- November 2017. However, in WY 2018, measurements weren't reported until 1 December 2017
- and no station measurements were reported past 1 April 2017. The reporting period likely covered
- all the snowfall events, but not all the precipitation events.
- 291 To address the rainfall measurement and reporting issues, we used GLDAS NOAH v2.1 (Rodell
- et al., 2004) rainfall + snowfall from the nearest grid cell (1/4° spatial / 3 hr temporal resolution)
- 293 to fill in precipitation prior to the first measurements in each water year, and after 4-1 for both
- water years. We did not account for rain from 10 November 2016 to 1 April 2017 and from 1
- 295 December 2017 to 1 April 2018; instead we relied on the modeled precipitation from SNOWPACK
- using snow depth. The AKAH station observations show that rain during this time period was rare.
- 5) A database problem prevented snow heights > 100 cm from being entered into the database for a few days in 2017. This problem became apparent during February 2017, when the Nuristan
- avalanches took place (United Nations, 2017), as that is the first time that most stations
- recorded values > 100 cm. Values were shown as 100 cm on multiple days followed by values > 100 cm. To address this issue, we flagged all the values equal to 100 cm prior to peak snow
- depth in 2017, then marked those as null values. We then filled those null values using the
- cumulative sum of new snow during that time.
- 304 5.6 Analysis of modeled snow profiles
- For holistic measures of the snow profiles modeled in Alpine3D, we used two metrics from
- Bellaire et al. (2018): 1) fraction of facets and 2) number of critical layers. Fraction of facets is the
- height of all the layers containing faceted crystals, i.e. International Classification for Seasonal
- 308 Snow on the Ground primary codes FC, DH, and SH (Fierz et al., 2009), divided by the height of
- 309 the snowpack. The number of critical layers was computed using a threshold sum approach
- 310 (Schweizer and Jamieson, 2007) with modifications for simulated profiles (Monti et al., 2014
- Table 1). In each profile, 6 different variables (grain size, difference in grain size, hardness,
- difference in hardness, grain type, and depth) in the top meter of the snowpack (from the surface)
- were checked against threshold values. Layers exceeding 5 or more thresholds were classified as
- 314 critical.
- 315 The fraction of facets metric does not have a validation study, but faceted layers are a weak crystal
- form and are responsible for 43% (Bair et al., 2012) to 67% (Schweizer and Jamieson, 2001) of
- 317 investigated avalanches. Layers classified as critical using the threshold sum approach above
- 318 corresponded to failure layers about half of the time to failure layers found with Compression Tests
- 319 (Monti et al., 2014), an in situ snowpack stability test (van Herwijnen and Jamieson,
- 320 2007; Jamieson, 1999).

5.7 Spatial scale for comparisons

321

335

339

340

341

342

322 Because ParBal is the only model run at 500 m spatial resolution and all the other models were run 323 at ~ 25 km, it is the only model appropriate for point comparisons, although point to area problems 324 are still an issue. To address the geolocational uncertainty for the gridded MODIS products, which 325 can be up to one ~500 m pixel (Tan et al., 2006; Xiaoxiong et al., 2005) and spatial variability of the snow, we used a 9-pixel neighborhood centered on each AKAH station and chose the best fit 326 327 to the SNOWPACK modeled SWE. This approach has been used in previous work (Bair et al., 328 2018a;Rittger et al., 2016). We also include the high and low SWE values in that surrounding 9-329 pixel neighborhood to bound the uncertainty.

For all of the other model comparisons, we resampled all of the model output to a UTM (Zone 43S) grid with 25 km pixels, close to the native resolution of the NOAH-MP and GLDAS2 grid used (0.25°). This yielded a study area of 105,625 km² (13 x 13 pixels, each 25 km² in area). The ParBal output had to be significantly upscaled from 500 m to 25 km using Gaussian Pyramid reduction (Burt and Adelson, 1983) in steps with bilinear interpolation for the final step.

6 RESULTS AND DISCUSSION

The relationships between the components are summarized in Figure 2. The results discussed below are comparisons of: 1) SWE and 2) snow stratigraphy across a) all of the AKAH stations (points) and b) the entire study region.

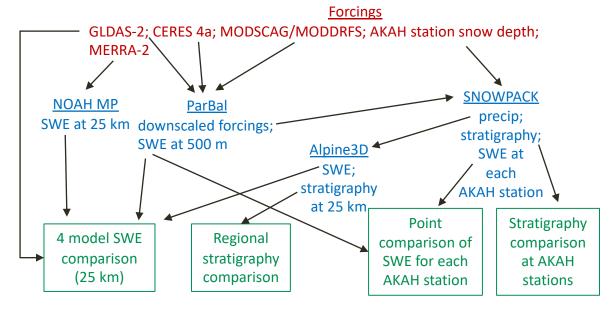

Figure 2 Summary of relationships between the various components. Forcings are shown in red, models and selected outputs are shown in blue, and the comparisons discussed below are shown in green. The black arrows show the direction of inputs.

6.1 Point comparisons between SNOWPACK and reconstructed SWE

A first step for any SWE reconstruction comparison is to determine when the ablation season starts. This varies for different years and at different sites (e.g. Margulis et al., 2016). Using the

SNOWPACK modeled SWE, we can examine the peak SWE dates for both years for all of the AKAH stations (Figure 3ab). Peak SWE dates vary across the stations and years, but the median values between years are a week apart, 19 February 2017 and 26 February 2018. Thus, we use those dates for our comparisons.

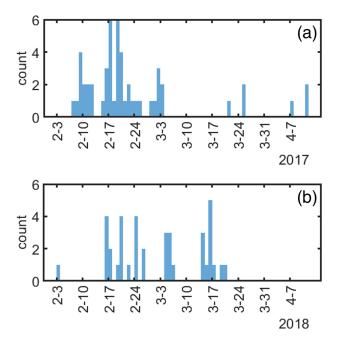

Figure 3 Peak SWE dates, modeled by SNOWPACK for 2017 (a) and 2018 (b) for each of the AKAH stations. The median peak SWE dates are 19 February 2017 and 26 February 2018. N=52 and 41 AKAH stations used for 2017 and 2018.

To create a holistic comparison for all the stations across the ablation period, mean SWE values were computed and plotted for each day during the ablation season (Figure 4). For the reconstructed SWE on 19 February 2017, the bias is -77 mm (-28%). For the reconstructed SWE on 26 February 2018, the bias is -6 mm (-9%). Thus, together these biases average to -42 mm (-19%). The high/low values in the 9-pixel neighborhood show the wide spatial variation in SWE estimates, and are to be expected in these deep valley sites (Section 6.2). The increases in reconstructed SWE during the ablation season are caused due to differences in how melt is summed for any given pixel. In ParBal, melt is only summed during periods of contiguous snow cover. This means that if a pixel containing an AKAH station has no snow on it at some point during the ablation season, but then snow is detected, it causes an increase in the mean SWE. This is called an ephemeral snow event, i.e. snow that disappears and reappears. For a more in depth examination of the error at individual stations, a box plot is shown for the median peak SWE dates for both years (Figure 5). The median bias of the reconstructed SWE is -11 mm (-14%).

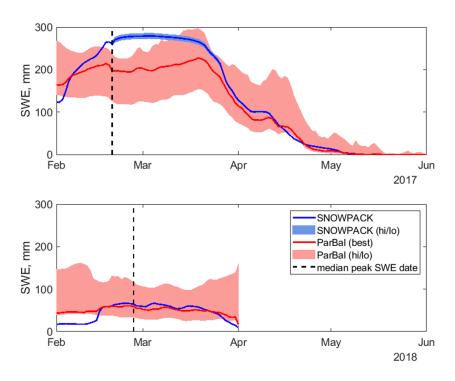

Figure 4 Mean SWE for 2017 (a) and 2018 (b) modeled at all of the AKAH stations using SNOWPACK (blue lines) compared to reconstructed SWE from ParBal using a best of 9-pixel approach (red lines). Also plotted is the median peak SWE date. The hi/lo bounds (filled areas) represent uncertainty. For ParBal, uncertainty is expressed as the range of values in the 9 pixel neighborhood. For SNOWPACK, uncertainty is 5% of the modeled SWE during the ablation season. See Sections 5.1 and 5.2 for details. The modeled SWE values end abruptly on 1 April 2018 because the AKAH stations stopped reporting due to drought conditions. The number of stations used is the same as in Figure 3.

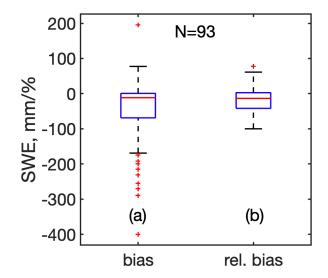

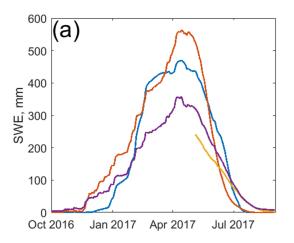

Figure 5 Bias (a) and relative bias (b) for ParBal reconstructed SWE vs Alpine 3D modeled SWE at AKAH stations on the median peak SWE date for both years, where bias here is ParBal SWE – Alpine 3D SWE.

6.2 Four model spatial comparisons

 The AKAH stations are lower than the average elevation for the region. The average elevation of the AKAH stations is 2619 m (1735 to 3410 m). But when the 500 m DEM is upscaled to 25 km, the average elevation of the pixels containing the AKAH station is 3858 m with a range of 2517 to 4764 m. This has two important implications: 1) much of the higher elevation snowfall is being extrapolated and 2) the higher elevation causes the peak SWE date to move forward in time. The median peak SWE dates for the (N=169) 25 km pixels encompassing the study area are 5 May 2017 and 3 May 2017. Thus, we use the median of the two to compare our reconstructed SWE values (Figure 6ab, Figure 7a-d, and supplementary video).

Striking is the range between models. NOAH-MP has the highest peaks (562 mm in 2017 and 331 mm in 2018), but is among the first to melt out. The reconstructed SWE from ParBal only shows minor variation between the 2017 peak (240 mm) and the 2018 peak (206 mm). ParBal and GLDAS-2 melt snow out latest in both years. This is especially true for ParBal in 2017, where the supplementary video shows that ParBal has snow cover over more pixels that persists for longer into the melt season, but is lower in SWE than the other models. The Alpine 3D model shows the second highest peak SWE in 2017 (469 mm), but the lowest peak (165 mm) in 2018. The comparatively higher values from NOAH-MP could result from relatively high precipitation estimates from its MERRA2 precipitation forcings. Similarly, Viste and Sorteberg (2015) report that MERRA (version 1) showed higher snowfall in the Indus Basin than any other reanalysis or observation-based forcings dataset.

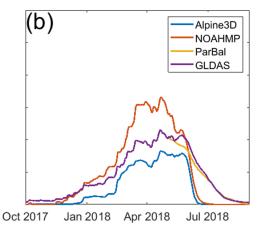

Figure 6 Time series of mean SWE for four snow models across the study area (13x13x25 km pixels) shown in Figure 1 for 2017 (a) and 2018 (b). The reconstructed SWE from ParBal (yellow) goes back to 4 May, the median peak SWE date for both years, since reconstruction is only valid during the ablation season.

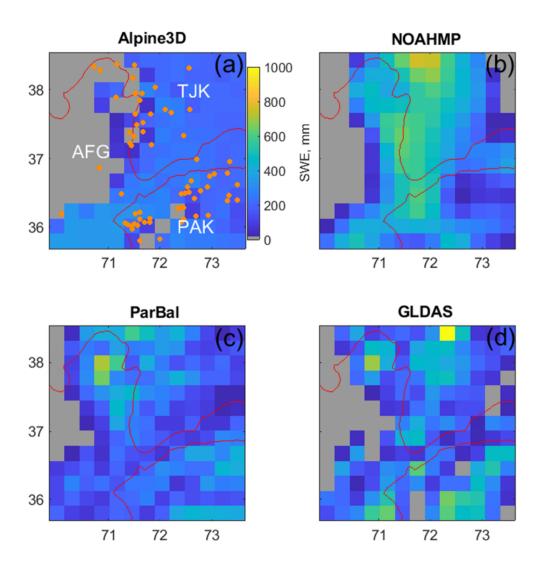

Figure 7 Four model (a-d) spatial comparison for the study area on 4 May 2018. The white letters are: AFG-Afghanistan; TJK-Tajikistan; and PAK-Pakistan. Also shown in (a) are the locations of the AKAH stations (orange points). This is a frame from a video sequence available as supplementary material.

Since Alpine3D is relying heavily on extrapolation of SWE, we suggest its mean SWE values plotted in Figure 6 could have higher uncertainty than some of the other models. For example, the Alpine3D pixels seem to melt out early compared to the other models, especially ParBal, which is the only model relying on satellite-based estimates of fSCA (see supplementary video). Thus, Alpine3D may computing too little SWE in cold, high elevation areas that melt slowly. These problems are all indicative of stations that are located in valley bottoms and that only cover the lowest elevations across these 25 km pixels.

The ParBal results are confounding given that the agreement between the modeled SWE from ParBal and SNOWPACK at individual AKAH stations (Figure 4ab) is much better for both 2017 and 2018.

For insight into potential biases in the modeled spatial SWE from ParBal, we carefully studied the snow-covered area (SCA, not just for 2017 & 2018, but since 2001), the potential melt (i.e. the melt if a pixel were 100% snow covered), and the melt from glacierized areas (light blue in Figure 1). We did not find any errors in the model, its parameters, or its forcings. Thus, it is possible that the ParBal SWE is low-biased in 2017 for reasons that we could not discern, or that the other models are high biased. Of note is that the 2017 & 2018 SCA (Figure 8 purple and orange) is very similar for both years during the ablation period, especially at the end of the ablation season.

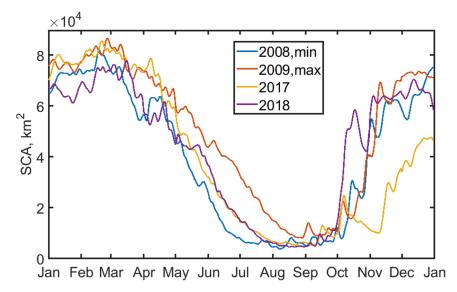

Figure 8 Time series of snow covered area from spatially and temporally interpolated MODSCAG (Rittger et al., in press), an input for ParBal, for four selected years across the region. Years 2008 and 2009 had the lowest and highest values on July 1 over the period of record from 2001 to 2018, while 2017 and 2018 comprise the AKAH station study period.

Since pixels do not contribute uniformly to melt, SCA alone cannot be used to predict SWE, but in general years with less snow have lower SCA values towards the end of the ablation season. Figure 8 shows that 2017 and 2018 were similar in terms of SCA from April through melt out. Thus, the large difference between 2017 and 2018 for the AKAH station SWE, but small differences in SCA and spatially-averaged reconstructed SWE, suggest that 2017 may have been a larger snow year at the lower elevations where the AKAH stations are, but similar to 2018 at the higher elevations.

6.3 Stratigraphy and stability

The simulated snow profiles from the AKAH stations (Figure 9ab) and the 25 km pixels containing the AKAH stations (Figure 10ab) show very different snowpacks. Because of the induced increase in elevation from scaling (e.g. from an average of 2619 m to 3858 m, Section 6.2), the 25 km pixels show a deeper, but more faceted snowpack with critical layers that persist for a month or longer. In 2017, for the median AKAH station values, the snowpack reaches a maximum of 76% facets

on January 21 (Figure 9a). In 2018, the snowpack reaches a maximum of 71% facets (Figure 9b). There were no critical layers simulated. In contrast, for the median values in the 25 km pixels for both years, the height of snow (HS) is approximately 2 × that for the stations (Figure 10ab). The snowpack reaches a maximum of 94% facets in 2017, with one critical layer persisting for 35 days (Figure 10a). The snowpack in 2018 reaches 95% facets with 1 or 2 critical layers persisting for 80 days (Figure 10b). During the Nuristan avalanches on 4 February to 7 February 2017 that killed over 100 people (United Nations, 2017), the AKAH stations show the largest 3-day snowfall of the study period (Figure 9a) and the results for the 25 km pixels show that large snowfall occurring on top of the only critical layer of the season (Figure 9b). That is a classic avalanche scenario, i.e. a large snowfall on a weak snowpack.

In lieu of any type of snow profile from this region, these profiles paint the best picture of the snow conditions available. A relatively stable snowpack seems to be present in the valleys, where the AKAH stations are located. But at the higher elevations, the simulated profiles show a more critical snowpack. This is especially serious considering these villages are in the runout zones of these potentially unstable snowpacks. In some cases, several thousand meters of vertical relief loom above the villages. For example, Yarkhun Lasht (36.795N 73.022E, el. 3249 m) in Pakistan is flanked by 6500 m peaks on both side of its valley.

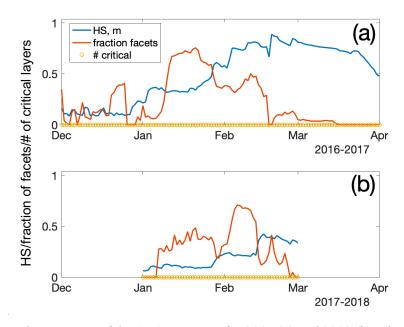

Figure 9 Stratigraphy summary of the AKAH stations for 2017 (a) and 2018 (b). Plotted are the median: height of snow (HS); fraction of the snowpack containing facets; and number of critical layers. The number of stations used to compute the medians varied due to snow coverage.

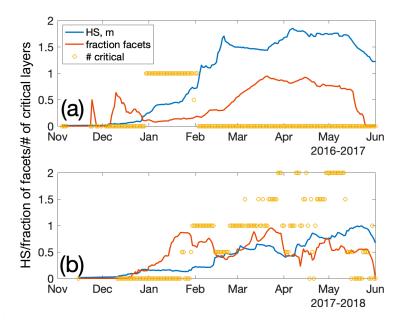

Figure 10 Stratigraphy summary of the (13x13) 25 km pixels containing AKAH stations for 2017 (a) and 2018 (b). Plotted are the median: height of snow (HS); fraction of the snowpack containing facets; and number of critical layers.

7 CONCLUSION

Knowledge of the snowpack in northwestern High Mountain Asia is poor. This area is subject to droughts and threatened by snow avalanches. Both problems can be aided by improved knowledge of the snowpack. Thanks to a novel operational avalanche observation network, there are now daily snow measurements at a number of operational weather stations in this austere region. In this study, two years of daily snow depth measurements from these stations were combined with downscaled reanalysis and remotely-sensed measurements to force a point and spatially distributed snow model. Compared to a previous effort (Bair et al., 2018a), this study represents a substantial improvement in SWE modeling for the region, and a first attempt to characterize region-wide snow stratigraphy. At the point scale, SWE estimates from a reconstruction technique that does not use precipitation or in situ measurements compared favorably. At the regional scale, four models showed a wide spread in both peak SWE and melt timing. For the models that rely on in situ precipitation measurements, a major challenge is spatial extrapolation, as many of the stations are located in deep valleys. Adding measurements from the mountains above would facilitate more realistic lapse rates, but these measurements do not currently exist, although they would be beneficial both for operational avalanche safety and for scientific studies.

In the regional comparison, SWE estimates from ParBal were on the low end, but given the model spread it is difficult to form a consensus estimate. We plan additional in situ validation at other sites in High Mountain Asia to continue to assess the performance of ParBal there.

The simulated profiles showed very different snowpacks. At the point scale at lower elevations in the valleys, profiles showed fewer facets and almost no critical layers, while at the regional scale

- for higher elevations, the profiles showed heavily faceted snowpacks with critical layers that
- persisted throughout the winter and spring.

APPENDIX A Detailed model forcings and parameters

473 PARBAL

- ParBal was configured and forced as described in Bair et al. (2018a); Bair et al. (2016). The model
- 475 time step was 1 hr. The DEM used was the ASTER GDEM version 2 at 1 arc sec (NASA JPL,
- 476 2011), while the canopy type and fraction were taken from the Global Land Survey at 30 m (USGS,
- 477 2009). The shortwave and longwave forcings were downscaled from the CERES SYN edition 4a
- 478 1°/1 hr product (Rutan et al., 2015), while the air temperature, specific humidity, air pressure, and
- wind speeds were downscaled from the GLDAS NOAH version 2.1 0.25°/3 hr product (Cosgrove
- et al., 2003). Time-space smoothed (Dozier et al., 2008; Rittger et al., in press) fSCA and grain size
- 481 from MODSCAG (Painter et al., 2009) was combined with the visible albedo degradation from
- dust in MODDRFS (Painter et al., 2012) to produce snow hourly snow albedo.
- 483 NOAH-MP
- NOAH-MP v3.6 was run in retrospective mode within the NASA Land Information System (LIS)
- framework. A state vector ensemble (total 30 replicates) was generated by perturbing the forcings
- 486 to account for the state uncertainty during forward propagation of the model. MERRA-2 (Gelaro
- et al., 2017) forcings were utilized with bilinear spatial and linear temporal interpolation. The
- 488 model was run on an equidistant cylindrical grid with 0.25° spatial resolution and a 15 min model
- timestep. The spin-up time extended from May 2002 to May 2016 while the study period was from
- June 2016 to October 2018. The number of maximum layers in the snowpack was 3. Table A1
- 491 provides details of the NOAH-MP scheme options selected. Further details regarding each scheme
- and relevant references can be found at: https://ral.ucar.edu/solutions/products/noah-
- 493 multiparameterization-land-surface-model-noah-mp-lsm.

| Physical process/ parameter | Scheme used |
|---|---|
| Elevation data | SRTM Native |
| Landcover data | MODIS Native (IGBPNCEP) |
| Slope, Albedo and Greenness data | NCEP Native |
| Bottom temperature (lapse-rate correction) | ISLSCP1 |
| Vegetation | dynamic |
| Canopy stomatal resistance | Ball-Berry |
| Runoff and groundwater | SIMGM |
| Surface layer drag coefficient | M-O (General Monin-Obukhov similarity theory) |
| Supercooled liquid water and frozen soil permeability | NY06 |
| Radiation transfer | gap=F(3D;cosz) |
| Snow surface albedo | BATS (Biosphere-Atmosphere Transfer Scheme) |

| Rainfall and snowfall | Jordan91 |
|------------------------------------|---------------|
| Snow and soil temperature time | semi-implicit |
| Lower boundary of soil temperature | Noah |

495 SNOWPACK

502

503

504

505

506

SNOWPACK v3.50 was run in research mode at a 15 min timestep with hourly outputs for each of the AKAH stations. Hourly forcings were computed by combining temporally interpolated snow depth from the AKAH manual measurements with: air temperature, incoming shortwave, reflected shortwave, incoming longwave, wind speed, and relative humidity from the downscaled ParBal outputs, as described in Section 5.2. SNOWPACK was only run for periods when measurements from the AKAH stations were available, Nov/Dec to April/May, depending on the year.

Plots were assumed to be level, so forcings without terrain correction were applied except for shading when the sun was below the local horizon, e.g. a mountain blocking the sun (Dozier and Frew, 1990). The wind direction, which is not available in GLDAS-2, was fixed at the mean value from the daily AKAH instantaneous values. The ground temperature was set as the minimum of the air temperature or -1.5°C when snow cover was present.

Aside from setting required parameters and values for inputs and outputs, changes to default parameters that affected model output are provided in Table A2:

| Parameters | Value | Description |
|-------------------------------|---------------|-----------------------------|
| TS_DAYS_BETWEEN | 0.014666 days | Output hourly values |
| PRECIP_RATES | FALSE | Output is provided a |
| | | summed precipitation over |
| | | the output timestep (1 hr) |
| SW_MODE | BOTH | Both incoming and |
| | | reflected (incoming x |
| | | albedo) are provided |
| HEIGHT_OF_METEO_VALUES | 2 m | Height of meteorological |
| | | measurements |
| HEIGHT_OF_WIND_VALUE | 2 m | Height of wind |
| | | measurements |
| ENFORCE_MEASURED_SNOW_HEIGHTS | TRUE | Precipitation is calculated |
| | | using HS |
| ATMOSPHERIC_STABILITY | NEUTRAL | Neutral conditions are |
| | | often present in moderate |
| | | to high wind speeds for |
| | | mountain terrain (Lehning |
| | | et al., 2002a;Mitterer and |
| | | Schweizer, 2013) |
| MEAS_INCOMING_LONGWAVE | TRUE | Default is to estimate |
| | | emissivity of the air and |
| | | incoming longwave from |

| other measured parameters (FALSE). Here we provide longwave forcings |
|--|
| (TRUE). |

509 Table A2 Model parameters for SNOWPACK

510 ALPINE3D

- Alpine3D version 3.10 was run using with the outputs produced by SNOWPACK as forcings for
- each of the AKAH stations at 25 km resolution. The DEM and land cover (incorrectly labeled land
- use in the Alpine3D documentation) data were upscaled from the ParBal data. Alpine3D was run
- at an hourly timestep using hourly forcings, with daily outputs using the "enable-eb" switch. Other
- switches were set to off, the defaults. The "enable-eb" switch computes the terrain radiation with
- shading and terrain reflections (see Alpine 3D documentation at https://models.slf.ch for a
- 517 description).
- To extend the length of the model runs, for each AKAH stations, GLDAS-2 precipitation was
- appended to periods prior to the first AKAH observation for the year and after the last, as described
- 520 in Section 5.5.
- 521 The forcings were hourly: incoming shortwave, incoming longwave, air temperature, relative
- humidity, wind speed, wind direction, reflected shortwave, accumulated precipitation, and ground
- 523 temperature.
- 524 Critical to Alpine3D are the interpolation methods from MeteoIO to spatially distribute
- 525 precipitation and other forcings. We found the modeled SWE to be highly dependent on the spatial
- 526 interpolation of precipitation. Our initial approach was to explore local (i.e. with a given radius
- from a station) and regional (i.e. all AKAH stations) lapse rates in the measured snow depth and
- 528 modeled precipitation from SNOWPACK. We found almost no correlation in many of the
- 529 measurements, not surprising given the complexity of the terrain and likely existence of
- microclimates with substantial influence on precipitation. Without having a good validation source
- for spatial precipitation (as is the case for all of High Mountain Asia), we selected an interpolation
- method that yielded relatively smooth results, but showed increases in precipitation with elevation.
- Ultimately, we decided to use an inverse distance weighting scheme with elevation detrending
- 534 (IDW LAPSE) and a multilinear option. For this method, the input data are detrended, then the
- residuals are spatially interpolated according to an inverse distance weighting scheme. The
- detrending uses a multiple linear regression with northing, easting, and altitude. The linear
- regression has an iterative method for removing outliers. Finally, values at each cell are retrended
- using the multiple linear regression and added to the interpolated residuals.
- A summary of the interpolation methods, all of which are defined in the MeteoIO documentation
- 540 (Bavay and Egger, 2014), is given in Table A3.

| Forcing | Spatial interpolation method | Description and notes |
|-----------------|------------------------------|---|
| Air temperature | IDW_LAPSE | Inverse distance weighting with elevation detrending. |

| Accumulated precipitation | IDW_LAPSE with multilinear option set to TRUE | See notes above |
|-----------------------------|---|---|
| Relative Humidity | LISTON_RH | See Liston and Elder (2006) |
| Precipitation phase | PPHASE | Simple splitting at 274.35K |
| Wind speed | IDW_LAPSE | See above |
| Incoming longwave radiation | AVG_LAPSE | Average filling with elevation lapse rate |
| Wind direction | CST | Constant, fixed at average value from AKAH station instantaneous measurements |
| Pressure | STD_PRESS | Standard atmospheric pressure with elevation |

- 541 Table A3 Spatial interpolation methods for Alpine3D
- The same parameters as in Table A2 for SNOWPACK were used in Alpine3D with changes shown
- in Table A4. Other parameters were defaults.

| Parameters | Value | Description |
|-------------------------------|--------|--|
| CALCULATION_STEP_LENGTH | 60 min | 1 hr model timestep |
| ENFORCE_MEASURED_SNOW_HEIGHTS | FALSE | Use accumulated precipitation estimate from SNOWPACK |
