7  
8           **Abstract**

9           The eXtensible Bremen Aerosol/cloud and surfaceE parameters Retrieval (XBAER) algorithm  
10          has been designed for the Top-Of-Atmosphere reflectance measured by the Sea and Land  
11          Surface Temperature Radiometer (SLSTR) instrument onboard Sentinel-3 to derive snow  
12          properties: Snow Grain Size (SGS), Snow Particle Shape (SPS) and Specific Surface Area (SSA)  
13          under cloud-free conditions. This is the first part of the paper, to describe the retrieval method  
14          and the sensitivity study. Nine pre-defined SPSs (aggregate of 8 columns, Drontal, hollow  
15          bullet rosettes, hollow column, plate, aggregate of 5 plates, aggregate of 10 plates, solid bullet  
16          rosettes, column) are used to describe the snow optical properties. The optimal SGS and SPS  
17          are estimated iteratively utilizing a Look-Up-Table (LUT) approach. The SSA is then  
18          calculated using another pre-calculated LUT for the retrieved SGS and SPS. The optical  
19          properties (e.g., phase function) of the ice crystals can reproduce the wavelength-  
20          dependent/angular-dependent snow reflectance features, compared to laboratory measurements.  
21          A comprehensive study to understand the impact of aerosol, SPS, ice crystal surface roughness,  
22          cloud contamination, instrument spectral response function, snow habit mixture model, and  
23          snow vertical inhomogeneity on the retrieval accuracy of snow properties has been performed  
24          based on SCIATRAN radiative transfer simulations. The main findings are (1) Snow angular  
25          and spectral reflectance feature can be described by the predefined ice crystal properties only  
26          when both SGS and SPS can be optimally and iteratively obtained; (2) The impact of ice crystal  
27          surface roughness plays minor effects on the retrieval results; (3) SGS and SSA show an inverse  
28          linear relationship; (4) The retrieval of SSA assuming non-convex particle shape, compared to

29 convex particle (e.g. sphere) shows larger results; (5) Aerosol/cloud contamination due to  
30 unperfected atmospheric correction and cloud screening introduces underestimation of SGS,  
31 “inaccurate” SPS and overestimation of SSA; (6) The impact of instrument spectral response  
32 function introduces an overestimation on retrieved SGS, an underestimation on retrieved SSA  
33 and no impact on retrieved SPS; (7) The investigation, by taking a ice crystal particle size  
34 distribution and habit mixture into account, reveals that XBAER retrieved SGS agrees better  
35 with the mean size, rather than the mode size for a given particle size distribution.

36

## 37 **1 Introduction**

38 Snow properties such as snow albedo, Snow Grain Size (SGS), Snow Particle Shape (SPS),  
39 Specific Surface Area (SSA), snow purity (Warren and Wiscombe, 1980; Painter et al., 2003;  
40 Hansen and Nazarenko, 2004; Taillandier et al., 2007; Gallet et al., 2009; Battaglia et al., 2010;  
41 Gardner et al., 2010; Domine et al., 2011; Liu et al., 2012; Qu et al., 2015; Baker et al., 2019;  
42 Pohl et al., 2020a) show large variabilities temporally and spatially (Kukla et al., 1986). They  
43 play important roles in the global radiation budget, which is critical to some well-known  
44 phenomenon such as the Arctic amplification (Serreze and Francis, 2006; Domine et al., 2019).  
45 Satellites offer an effective way to understand the surface-atmosphere processes and  
46 corresponding feedback mechanisms on the regional, continental and/or global scales (Konig  
47 et al., 2001; Pope et al., 2014). Satellite derived snow products (e.g., SGS, SPS, and SSA) are  
48 particularly important for short-term hydrological, meteorological and climatological  
49 modelling (Livneh et al., 2009). A high-quality snow property data product can also be applied  
50 to derive Aerosol Optical Thickness (AOT) over cryosphere (Mei et al., 2020a). High-quality  
51 satellite derived snow products and their by-products are also important for the creation of long-  
52 term “Climate Data Records“ (SSMC, 2014), which enable a better investigation and  
53 interpretation concerning global climate change (Konig et al., 2001). However, both the  
54 definition and the corresponding data accuracy of SGS are poor (Langlois et al., 2020) while  
55 there is no existing SPS satellite product. The lack of good information on SGS and SPS leads  
56 to low quality of SSA (Gallet et al., 2009). The accuracy of SGS, SPS and SSA limits the model

57 performance for the prediction of snow properties related to climate change issues. Lack of  
58 information of SGS and SPS also restricts the accuracy of snow bidirectional reflectance  
59 estimation, which further limits the retrieval possibilities of aerosol and cloud properties above  
60 snow (Mei et al., 2020a, 2020b).

61 A comprehensive overview of remote sensing of SGS, SPS, and SSA can be found in  
62 many previous publications (e.g., Li et al., 2001; Stamnes et al., 2007; Koren, 2009; Lyapustin  
63 et al., 2009; Dietz et al., 2012; Wiebe et al., 2013; Frei et al., 2012; Mary et al., 2013;  
64 Kokhanovsky, et al., 2019; Xiong et al., 2018). The variation of SGS leads to the large  
65 variability of Top Of Atmosphere (TOA) reflectance in NIR/SWIR spectral ranges while SPS  
66 shows a strong impact on TOA reflectance at visible channels (Warren and Wiscombe, 1980).  
67 Different retrieval algorithms have been developed for different instruments. For instance, the  
68 MODIS Snow Covered-Area and Grain size (MODSCAG) retrieval algorithm and Multi-Angle  
69 Implementation of Atmospheric Correction (MAIAC) algorithm have been used to derive SGS  
70 using MODIS and VIIRS instruments (Painter et al., 2003; 2009; Lyapustin et al., 2009).

71 Snow particle shape is another important parameter which affects the estimation of snow  
72 properties, such as albedo (Räisänen et al., 2017; Flanner and Zender, 2006), because ice  
73 crystals with different shapes have different optical properties (Jin et al., 2008; Yang et al.,  
74 2013). The absorption and extinction cross-sections of an ice crystal can be described as a  
75 function of size, shape, and refractive index at a given wavelength (van de Hulst 1981;  
76 Mischenko et al., 2002 and references therein). Natural snow consists of grains, depending on  
77 temperature, humidity, and meteorological conditions, which have numerous different shapes  
78 (Nakaya, 1954). SPSs have been classified into different categories, the classification has been  
79 increased from 21 (Nakaya and Sekido, 1938) to 121 categories (Kikuchi et al., 2013). Although  
80 spherical shape assumption is typically used for field measurements (Flanner and Zender, 2006;  
81 Donahue et al., 2020), this approximation is not recommended to be used in retrieval algorithms  
82 of satellite measurements because it leads to large differences between observed and simulated  
83 wavelength-dependent snow bidirectional reflectance, especially at visible wavelengths  
84 (Leroux and Fily et al., 1998; Aoki et al., 2000; Jin et al., 2008; Dumont et al., 2010; Libois et  
85 al., 2013). Improper wavelength-dependent snow bidirectional reflectance caused by a

86 predefined SPS leads to low-quality satellite retrieval results. Some attempts to derive SPS in  
87 the ice cloud can be found in previous publications (McFarlane et al., 2005; Cole et al., 2014).

88 According to Legagneux et al., (2002), SSA is defined as the surface area of ice crystal  
89 per unit mass, i.e.,  $SSA = A_t/\rho V$ , where  $A_t$  and  $V$  are total surface area and volume, respectively,  
90  $\rho$  is the ice density. SSA includes information on both SGS and SPS and it is often used to  
91 describe the surface area available for chemical processes (Taillandier et al., 2007; Domine et  
92 al., 2011; Yamaguchi et al., 2019). SSA is reported to have a good relationship with snow  
93 spectral albedo at the short wave infrared wavelengths (Domine et al., 2007). Optical methods  
94 are routinely used to measure SSA in the field (Gallet et al., 2009). Empirical equations have  
95 been proposed to describe the change of SSA (Legagneux and Domine, 2005; Taillandier et al.,  
96 2007). Few attempts have been made to derive SSA from satellite observations (Mary et al.,  
97 2013; Xiong et al., 2018).

98 This paper presents a new retrieval algorithm to derive SGS, SPS, and SSA from satellite  
99 observations. In a snow-atmosphere system, satellite observed TOA reflectances are affected  
100 by numerous snow and atmospheric parameters. The parameters, which will be estimated in the  
101 framework of the eXtensible Bremen Aerosol/cloud and surface parameters Retrieval (XBAER)  
102 algorithm, will be called the target parameters. Other parameters, which the TOA reflectance  
103 also depends on, will be called the model parameters. In the case of the XBAER algorithm, the  
104 target parameters are SGS, SPS, and SSA, whereas the model parameters are aerosol loading,  
105 cloud optical thickness, and gaseous absorption. Throughout the paper, SGS will be  
106 characterized by an effective radius. Following Baum et al., (2011), the effective radius is  
107 defined as  $3V/(4A_p)$ , where  $V$  and  $A_p$  are the volume and average projected area, respectively.  
108 As can be seen, in the case of a spherical particle, the effective radius is equal to the radius of  
109 the sphere. The general concept of the retrieval algorithm is to use simultaneously spectral and  
110 angular reflectance measurements, which are sensitive to SGS and SPS. The spectral channels  
111 used in the XBAER algorithm are 0.55  $\mu\text{m}$  and 1.6  $\mu\text{m}$ . Both nadir and oblique observation  
112 directions from SLSTR are used. An optimal SGS and SPS pair is achieved by minimizing the  
113 difference between measured and simulated atmospheric-corrected surface reflectances. SSA  
114 is then calculated based on the retrieved SGS and SPS. Nine predefined SPSs (aggregate of 8

115 columns, droxtal, hollow bullet rosettes, hollow column, plate, aggregate of 5 plates, aggregate  
116 of 10 plates, solid bullet rosettes, column) (Yang et al., 2013, see Table 1) are used to describe  
117 the snow optical properties and to simulate the snow surface reflectance at 0.55 and 1.6  $\mu\text{m}$  at  
118 two observation angles.

119 Three points we would like to emphasize to avoid misunderstandings between snow  
120 science community and remote sensing community.

121 ➤ **Usage the Yang et al (2013) database for ice crystal in the air (ice cloud) and on**  
122 **the ground (snow).** The optical properties of ice crystals presented by Yang et al.,  
123 (2013) have been widely used to study ice clouds. In recent publications, it has been  
124 demonstrated that they can also be used for snow studies (Räsänen et al, 2015;  
125 Pirazzini et al., 2015; Saito et al., 2019; Schneider et al., 2019; Pohl et al., 2020b). In  
126 fact, the single-scattering properties of ice crystals in Yang et al., (2013) database are  
127 determined solely by given particle size, shape, and refractive index. They can be  
128 used to describe the optical properties of both snow particles and ice cloud particles  
129 when the particle models represent the aforementioned optical/physical properties  
130 (Saito et al., 2019; Personal communication with Dr. Saito).

131 ➤ **Snow particle shape observed from field measurements and derived from**  
132 **satellite observations.** For scientists working in a laboratory or on campaign-based  
133 studies, the best way to get an image of snow is to use an X-ray microtomography or  
134 confocal scanning optical microscope/scanning electron microscope (Hagenmuller et  
135 al., 2016; Baker et al., 2019; Personal communication with Dr. Ian Baker). In a field  
136 measurement and its related application areas (e.g., calculation of snow albedo), a  
137 spherical shape assumption is widely used because it is easier to derive other snow  
138 properties such as SSAs and snow albedo based on this assumption, compared to  
139 other more complicated shapes (see Appendix). The assumption of spherical and non-  
140 spherical shape has much less impact on the estimation of snow albedo compared to  
141 the bidirectional reflection features of snow (Grenfel and Warren, 1999; Dumont et  
142 al., 2010). Because SPS has a significant impact on the ice crystal phase function

143 while it has a relatively weak impact on the snow extinction/absorption coefficient  
144 (Jin et al., 2008). However, the spherical shape cannot be used to provide typical  
145 bidirectional reflection features of snow with required accuracy (Jin et al., 2008;  
146 Dumon et al., 2010; Jiao et al., 2019), which is the fundamental basis to derive snow  
147 properties from satellite remote sensing techniques. Thus, more complicated SPSs,  
148 such as those proposed by Yang et al (2013), are recommended to use in the  
149 simulations of the angular distribution of snow reflectance. Besides, both snow albedo  
150 and directional reflectance are affected by other factors such as how single particle  
151 aggregates;

152 ➤ **SGS and SSA.** Although the definition of snow grain constitutes is an ongoing debate  
153 in different communities, SGS and SPS are two fundamental inputs for any radiative  
154 transfer model, which is the basis for the satellite retrievals (Langlois et al., 2020).  
155 Typically, the SSA is more preferable within the snow science community because  
156 SSA is commonly used in further applications based on field measurements. We note,  
157 however, according to the definition of SSA, for a given SPS, a unique relationship  
158 between SGS and SSA can be derived. SPS is the intermediate but fundamental  
159 parameter needed to retrieve SSA in our XBAER algorithm.

160 This paper is structured as follows: observations characteristics of SLSTR and the  
161 laboratory measurements used for sensitivity studies are described in section 2. The theoretical  
162 background and the ice crystal database (Yang et al., 2013) are presented in section 3. Section  
163 4 describes the eXtensible Bremen Aerosol/cloud and surfaceE parameters Retrieval (XBAER)  
164 algorithm. The results of a comprehensive sensitivity study using SCIATRAN (Rozanov et al.,  
165 2014) simulations are presented in section 5. The conclusions are given in section 6.

171

172

173 **2 Data**

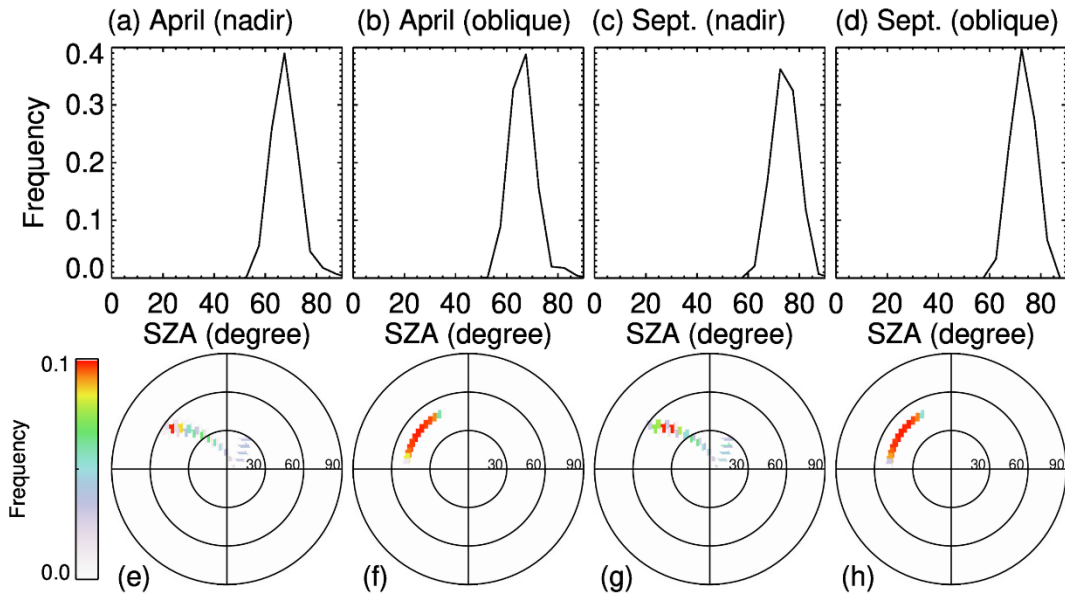

174 **2.1 SLSTR instrument**

175 The satellite data will be used twofold throughout the paper. In the first part, we perform a  
176 statistical analysis of the SLSTR observation/illumination geometries to select realistic settings  
177 for the sensitivity study. In the second part of the companion paper, the satellite measurements  
178 will be used as the inputs of the XBAER algorithm to derive the research satellite products of  
179 SGS, SPS, and SSA.

180 The SLSTR instrument onboard the European Space Agency (ESA) satellite Sentinel-3 is the  
181 successor of the Advanced Along-Track Scanning Radiometer (AATSR) instrument, which is used  
182 to maintain continuity with the (A)AATSR series of instruments. SLSTR takes the heritage of AATSR  
183 instrument characteristics, especially the dual-viewing observation capabilities and wavelength  
184 settings. In order to have a reasonable setting for observation/illumination geometries in the  
185 sensitivity study, we perform a statistical analysis of the SLSTR observation geometries (solar  
186 zenith angle, SZA, viewing zenith angle, VZA, relative azimuth angle, RAA), similar as Mei et al  
187 (2020a). This analysis is essential because 1) it provides a realistic setting of  
188 observation/illumination geometries in our sensitivity studies; 2) it helps us to have a complete  
189 understanding of the observation/illumination related surface/atmospheric properties. Here the  
190 definition of RAA has been harmonized with SCIATRAN (Roazanov et al., 2014), namely, RAA  
191 value is equal to  $0^\circ$  under strict glint condition. The statistical analysis has been performed using  
192 observations over Greenland during April and September 2017. April and September are reported  
193 to be representativeness months of the Arctic (Mei et al., 2020a). Please be noted that these two  
194 months are picked up to represent the SLSTR observation characteristic with typical solar  
195 illumination angle, the change of underlying surface properties plays no role in such selection. Fig.  
196 1 shows the frequency of SLSTR observation geometries. The upper panel shows the SZA with  
197 SLSTR nadir and oblique observations for April and September. We can see that the SZA occurs  
198 frequently with a value of  $70^\circ$  for selected months. The VZA and RAA for oblique observation mode  
199 are typically around  $55^\circ$  and in a range of  $[110^\circ, 170^\circ]$ , respectively. The observation geometries  
200 for nadir observation show relatively large variabilities due to larger swath width compared to  
201 oblique (1400 km vs 700 km). Larger SZA can be found especially at the edge of the swath. The  
202 VZA and RAA for oblique observation mode are typically in ranges of  $[0^\circ, 55^\circ]$  and  $[70^\circ, 140^\circ]$ ,  
203 respectively. According to the statistical analysis, a combination of SZA, VZA, RAA of  $70^\circ, 30^\circ,$   
204  $135^\circ$  for nadir observation and  $70^\circ, 55^\circ, 135^\circ$  for oblique observation can be a reasonable setting  
205 for the SLSTR observation geometries for the sensitivity study.

206

207

208 Fig. 1 Upper panel is the histograms of SZA for SLSTR observations: (a) nadir during April;  
 209 (b) oblique during April, (c) nadir during September; (d) oblique during September. Lower  
 210 panel is the polar plots of (VZA, RAA) probability for AATSR observations: (e) nadir during  
 211 April; (f) oblique during April, (g) nadir during September; (h) oblique during September.

212

## 213 2.2 Laboratory measurements

214 Laboratory measurements of the bidirectional reflectance of snow samples contain important  
 215 information about the dependence of the angular structure of snow reflection on the lighting  
 216 geometry, wavelength, and snow physical properties. The comparison of measured and  
 217 modeled bidirectional reflectance helps to establish the conceptual ideas for the retrieval  
 218 algorithm. For this comparison, we have selected measurements of fresh and aged snow  
 219 samples presented by Dumont et al., (2010) and Peltoniemi et al., (2009), respectively.

220 The fresh snow sample, a cylinder of 30 cm diameter and 12 cm height, was taken from  
 221 new wet snow layer at Col de Porte (Chartreuse, France) at 1300 meter above sea level during  
 222 January 2008 (Dumont et al., 2010). The sample was stored in a cold room at -10°C for one  
 223 week to avoid metamorphic effects during the ensuing measurements. To obtain the  
 224 Bidirectional Reflectance Factor (BRF), the snow sample was illuminated by a monochromatic  
 225 light source at incidence zenith angle of 60°. The spectral BRF between 500 and 2600 nm was  
 226 measured at viewing zenith angles of 0°, 30°, 60°, 70° and relative azimuth angles 0°, 45°, 90°,

227 135°, 180° by a spectrogonio-radiometer developed at the Laboratoire de Planétologie de  
228 Grenoble, France, and using a Spectralon® and an infragold® sample as a reference (see  
229 Dumont et al., (2010) for further details).

230 The aged snow sample, a cuboid of more than 10 cm height, was taken from an old dry  
231 snow layer at Masala, Finland, and brought into a warm laboratory. The spectral BRF between  
232 350 and 2500 nm was measured during the aged process by the Finnish geodetic institute field  
233 goniospectro-polariphotometer (FIGIFIGO) and using a Labsphere Spectralon 99% white  
234 reference plate. For illumination, a 1000 W Oriel Research Quartz tungsten halogen lamp at a  
235 zenith angle of 60° was utilized (Peltoniemi et al., 2009). Spectral BRF was obtained at viewing  
236 zenith angles up to 70° in 1° resolution and at relative azimuth angles of 0°, 90°, 130°, 160°,  
237 180°, 270°, 310°, and 340°. The first and last measurements were done in the principal plane,  
238 indicating minor metamorphism in the snow layer during the measurement.

239  
240

### 241 **3 Dependence of snow reflectance on target parameters**

242 A comprehensive data library (Yang et al., 2013) containing the scattering, absorption, and  
243 polarization properties of ice particles in the spectral range from 0.2 to 15 µm was used to  
244 calculate radiative transfer through a snow layer (Pohl et al., 2020b). A full set of single-  
245 scattering properties is available for nine ice crystal habits presented in Table 1. The maximum  
246 dimension of each habit ranges from 2 to 10000 µm in 189 discrete sizes.

247 The optical properties of ice crystals depend on wavelength, ice crystal size, and shape.  
248 Maximal dependence of the single-scattering albedo on the particle size is observed in the  
249 spectral ranges where ice absorption cannot be neglected. The asymmetry factor depends on  
250 the particle size for the whole spectral range. This dependence can be weaker or stronger at a  
251 selected wavelength depending on SPS (see Yang et al., (2013) for details).

252 To better illustrate the impact of SGS and SPS on the radiative transfer through a snow  
253 layer, we have calculated the reflectance of the snow layer consisting of droxtals, aggregates of  
254 8 columns, hollow columns, and plates with crystal surface roughness condition as severely  
255 roughened. The simulations of snow reflectance were performed using the radiative transfer

256 package SCIATRAN (Rozanov et al., 2014). The snow layer was defined as a layer directly  
257 over a black surface, with snow optical thickness of 500 and a snow geometrical thickness of  
258 1m. The snow layer is assumed to be vertically and horizontally homogeneous without any  
259 surface roughness and composed of monodisperse ice crystals. The impact of snow impurities  
260 and scattering/absorption processes in the atmosphere was neglected at this stage. The  
261 reflectance of the snow layer as a function of the effective radius of ice crystal at wavelengths  
262 0.55  $\mu\text{m}$  and 1.6  $\mu\text{m}$  is presented in Fig. 2. The calculations were performed for typical SLSTR  
263 instrument observation/illumination geometries (see section 2.1), with SZA, VZA, and RAA  
264 equal to  $70^\circ$ ,  $30^\circ$ , and  $135^\circ$  (scattering angle  $129^\circ$ ).

265 There are a couple of criteria we considered for the selection of the optimal wavelengths  
266 (0.55  $\mu\text{m}$  and 1.6  $\mu\text{m}$ ) in XBAER algorithm, for the purpose of creating a long-term satellite  
267 snow properties dataset with good and stable accuracy.

268 ➤ Taking the overlap channels between AATSR and SLSTR because a consistent  
269 long-term satellite snow dataset is possible only when the same algorithm can be  
270 applied on both AATSR and SLSTR instruments. In particular, the overlap channels  
271 between AATSR and SLSTR are 0.55, 0.66, 0.87, 1.6, 3.7, 10.85, and  $12\mu\text{m}$ .

272 ➤ Picking up wavelengths, for which contribution of thermal emission can be  
273 ignored, then 0.55, 0.66, 0.87, and 1.6  $\mu\text{m}$  remain.

274 ➤ Deleting the channel  $0.66\mu\text{m}$  to avoid the potential impact of  $\text{O}_3$  absorption,  
275 after that, 0.55, 0.87, and 1.6  $\mu\text{m}$  remain.

276 ➤ Taking into account, that the retrieval algorithm is a two-stage algorithm, namely,  
277 first it uses channels with minimum impact of ice crystal shape to retrieve the grain  
278 size, and then it selects the shape using channels with minimum impact of grain size.  
279 Accounting for that the channel  $0.87\mu\text{m}$  is impacted by both size and shape, 0.55 and  
280  $1.6\mu\text{m}$  channels were picked up for the retrieval.

281 The right panel of Fig. 2 demonstrates the strong dependence of the snow layer reflectance  
282 at 1.6  $\mu\text{m}$  on the SGS. One can also see that the dependence of snow reflectance on SPS cannot

283 be neglected. In particular, the same reflectance can be obtained with a combination of different  
 284 SGS and SPS. For instance, one can see from the right panel of Fig. 2 that, the reflectance of  
 285 the snow layer consisting of droxtals with SGS=200  $\mu\text{m}$  or of plates with SGS=65  $\mu\text{m}$  equals  
 286  $\sim 0.035$  in both cases. Thus, assuming different SPSs, the values of retrieved SGS can differ 3  
 287 times. The left panel of Fig. 2 demonstrates the dependence of the snow layer reflectance at 0.55  
 288  $\mu\text{m}$  on SGS and SPS. It can be seen that the dependence of reflectance on SGS is very weak for  
 289 droxtals and aggregate of 8 columns. However, reflectance at 0.55  $\mu\text{m}$  decreases with an  
 290 increase of SGS for hollow columns and plates. The weak oscillations for the reflectances at  
 291 0.55  $\mu\text{m}$  can be explained by the joint impact of oscillations in the single-scattering albedo and  
 292 elements of the scattering matrix presented in the original database. Although the reason for the  
 293 oscillation in the database is unclear, it is unlikely due to physical phenomena (Dr. M. Saito ,  
 294 personal communication).

295  
 296 Fig 2. Reflectance of snow layer at 0.55  $\mu\text{m}$  and 1.6  $\mu\text{m}$  calculated assuming different SPS.  
 297 Observation/illumination geometry: SZA, VZA and RAA were set to 70°, 30° and 135°,  
 298 respectively.

299 To illustrate this point, the dependence of the phase function at  $129^\circ$  scattering angle on  
300 SGS is shown in the left panel of Fig. 3. The phase functions (F11 element of the scattering  
301 matrix) were extracted from the original database. According to the left panel of Fig. 3, the  
302 dependence of snow surface reflectance at  $0.55 \mu\text{m}$  on SGS and SPS is caused mainly by the  
303 phase function of ice crystal. Weak oscillations can also be found.

304 The above analysis shows that accurate retrieval of SGS requires adequate information  
305 about SPS and accounting for the dependence of the phase function on SGS. To better illustrate  
306 the impacts of SGS on ice crystal phase function, we calculated reflectance at  $1.6 \mu\text{m}$  with  
307 different SGS values. The right panel of Fig. 3 represents the reflectance of the snow layer,  
308 consisting of aggregates of 8 columns, calculated accounting for the dependence of the phase  
309 function on the effective radius (black line) and assuming constant phase function for three  
310 selected effective radii equal to 15, 150, and  $1150 \mu\text{m}$  (red, green, and blue lines, respectively).  
311 It can be seen that the accurate simulation of snow reflection requires accounting for the  
312 dependence of phase function on SGS.

313 The main findings of presented investigations can be formulated as follows:

- 314 ➤ reflectance of a snow layer depends on both SGS and SPS;
- 315 ➤ accurate simulation of snow surface reflectance requires accounting for the dependence of  
316 phase function on SGS;
- 317 ➤ spectral channels in the visible spectral range is more sensitive to SPS compared to SGS;
- 318 ➤ spectral channels in the near infrared spectral range is more sensitive to SGS compared to  
319 SPS.

323 Fig 3. Left panel: phase function at 0.55 μm for scattering angle of 129°, extracted from the  
 324 original database (Yang et al., 2013) as a function of effective radius. Right panel: reflectance  
 325 of snow layer at 1.6 μm consisting of aggregate of 8 columns, calculated assuming that: 1:  
 326 phase function depends on the effective radius (black line); 2: phase function is constant  
 327 corresponding to the effective radius 15μm (red line); 3: same as 2 but for effective radius of  
 328 150 μm (green line); 4: same as 2 but for effective radius of 1150 μm (blue line).

329

330 Although the global classification snow crystal, ice crystal, and solid precipitation  
 331 particles suggested in Kikuchi et al. (2013) consist of the 121 particle types, we restrict  
 332 ourselves, in the retrieval algorithm, with nine shapes of ice crystals, for which optical  
 333 characteristics are represented in database (Yang et al., 2013). And these nine shapes have been  
 334 proven to be used to reproduce typical wavelength/angular features of snow reflectance in  
 335 reality, especially from satellite observations (Räsänen et al., 2015; Pirazzini et al., 2015; Saito  
 336 et al., 2019; Schneider et al., 2019; Pohl et al., 2020b). To further illustrate that the selected  
 337 dataset is able to reproduce the BRF of different snow types, we compared the simulated and  
 338 measured BRF of fresh (Dumont et al., 2010) and aged (Peltoniemi et al., 2009) snow samples.

339 To reproduce the spectral BRF by SCIATRAN, we use the setup described above in this section  
 340 and adjust the SGS for each SPS by minimizing the deviation between simulated and measured  
 341 reflectance at 1.6  $\mu\text{m}$ . Figure 4 shows the simulated BRF in the principal plane at 0.55  $\mu\text{m}$  of  
 342 fresh and aged snow samples, as well as the respective measurements. The BRF is defined as  
 343  $\pi I/F$ , where I is the reflected radiance and F is the incident irradiance. According to Fig. 4(a),  
 344 for fresh snow, plates are the best shape to reproduce the measured BRF in the vicinity of the  
 345 forward scattering peak but plates underestimate the BRF at higher viewing zenith angles in the  
 346 backscattering region. Here, shapes of hollow bullet rosette, hollow column, aggregate of 10  
 347 plates exhibit better potential to simulate the fresh snow layer BRF. In the case of aged snow,  
 348 shapes of solid and hollow column, hollow bullet rosette, and aggregate of 5 and 10 plates  
 349 provide BRF values in conformity with respective measurements. However, they slightly  
 350 underestimate the BRF at high zenith angles in the backscattering region where aggregate of 8  
 351 columns can simulate the aged snow BRF better.

352  
 353 Fig. 4 The comparison of angle dependence of laboratory-measured and simulated snow  
 354 reflectance: (a) fresh snow sample; (b) aged snow sample. Symbols - measurements, lines -  
 355 simulations with SCIATRAN assuming different SPS (see legend).

356 The above analysis demonstrates that the selected database of SPS can be used  
 357 successfully to reproduce measured BRF of both fresh and aged snow samples. Similar results  
 358 were obtained by Pohl et al., (2020b). In this paper, top of atmosphere BRF at 865 nm derived  
 359 from POLARization and Directionality of the Earth's Reflectances 3 (POLDER-3) on  
 360 Polarization & Anisotropy of Reflectances for Atmospheric Sciences coupled with  
 361 Observations from a Lidar (PARASOL) measurements over a pure snow surface in Greenland

362 (70.5° N, 47.3° W) on 6 July 2008 were compared with the SCIATRAN simulations, using  
363 droxtals, solid bullet rosettes, and solid columns.

364 According to the above analysis, we can formulate the general algorithm to retrieve SGS  
365 and SPS from satellite observations. Satellite provides the wavelength-dependent TOA  
366 reflectance, for a given SGS and SPS pair, the minimization between satellite observed TOA  
367 reflectance and theoretical simulation is performed. The optimal SGS and SPS are obtained  
368 when the difference between observations and simulations reaches the predefined criteria. The  
369 SSA is then calculated by the retrieved SGS and SPS.

370

#### 371 **4 XBAER Algorithm**

372 The retrieval algorithm consists of three stages. The first stage includes the estimation of  
373 SGS using the effective Lambertian surface albedo after atmospheric correction for selected  
374 observation geometries and wavelengths. This step is performed based on the path radiance  
375 representation (Mei et al., 2017), in which the TOA reflectance can be described by the  
376 contribution from the atmosphere and the interaction between atmosphere and surface. The  
377 inverse to derive the surface reflectance from the satellite observed TOA reflectance is called  
378 the atmospheric correction. And due to certain assumptions in the path radiance  
379 representation, the derived surface reflectance is equivalent to the effective Lambertian  
380 surface albedo. The estimation of SGS is obtained solving the following minimization  
381 problem with respect to the effective radius,  $r$ , of snow crystals:

$$382 \quad \|\mathbf{A}_e - \mathbf{R}_s(r)\|^2 \rightarrow \min. \quad (1)$$

383 Here,  $\mathbf{A}_e$  and  $\mathbf{R}_s(r)$  are two vectors which components are the effective Lambertian  
384 surface albedo and the simulated snow reflectance, respectively. The dimension of these  
385 vectors is the number of wavelengths times the number of viewing directions.

386 The simulation of snow reflectance (components of vectors  $\mathbf{R}_s(r)$ ) was performed using  
387 the radiative transfer package SCIATRAN (Rozanov et al., 2014) as described in Section 3.

388 The optical properties of nine SPSs, listed in Table 1, were used for radiative transfer  
389 calculations.

390 The minimization problem formulated by Eq. (1) was solved separately for each SPS  
391 using Brent's method (Brent, 1973). The solution of the minimization problem for each  
392 crystal habit is characterized by the following residual:

$$393 \quad \Delta_i = \|A_e - R_s(r_i^*)\|^2, i = 1, 2, \dots, 9, \quad (2)$$

394 where  $r_i^*$  is the solution of minimization problem given by Eq. (1) for  $i^{\text{th}}$  shape of the ice  
395 crystal particle.

396 The second stage is the selection of such  $i$  (SPS) for which  $\Delta_i$  is minimal. This  
397 completes the retrieval process and enables the optimal SGS and SPS to be obtained.

398 The third stage is to calculate SSA for the retrieved SGS and SPS. To this end, let us  
399 rewrite the SSA introduced above in the following equivalent form:

$$400 \quad \text{SSA} = 3/\rho r \cdot (A_t/4A_p), \quad (3)$$

401 where  $r$  is the effective radius. According to Cauchy's surface area formula (Cauchy, 1841;  
402 Tsukerman and Veomett, 2016), the average area of the projections of a convex body is  
403 equal to the surface area of the body, up to a multiplicative constant. In our case, this results  
404 in  $A_t = 4A_p$  and SSA for convex particles such as droxtals, solid columns, and plates are  
405 equal to  $3/\rho r$ . In the case of non-convex particles, the calculation of SSA requires the  
406 information about total area  $A_t$ . Although the database given by Yang et al. (2013) does not  
407 contain information about  $A_t$ , the total area of non-convex particles can be calculated  
408 employing geometric parameters of ice crystal habits presented in Table 1 of Yang et al.  
409 (2013). Here we take a typical SPS, aggregate of 8 columns, as an example, to show the  
410 difference between SSA calculated assuming convex and non-convex particle.

411 According to M. Saito (private communication), the parameters  $L$  and  $a$  of the  
412 aggregate of 8 columns (see Fig. 3 in Yang et al (2013) for details) can be obtained by

413 scaling with respect to the maximum dimension,  $D$ . To find these values for different  
 414 maximal dimensions, we calculate at first the volume of aggregate of 8 columns  
 415 corresponding to parameters  $a$  and  $L$  on a relative scale as given in Table 1 of Yang et al  
 416 (2013).

$$417 \quad V_r = \frac{3\sqrt{3}}{2} \sum_{i=1}^8 a_i^2 L_i. \quad (4)$$

418 Using the database of Yang et al (2013), one can obtain the maximal dimension,  $D_r$ ,  
 419 corresponding to the volume,  $V_r$ . Introducing the scaling factor,  $C_k = D_k/D_r$ , we have semi-  
 420 width and length for the aggregate with the maximal dimension  $D_k$ :

$$421 \quad a_{i,k} = a_i C_k, \quad L_{i,k} = L_i C_k. \quad (5)$$

422 The total surface of the aggregate on relative scale is given by

$$423 \quad S_r = 3 \sum_{i=1}^8 (\sqrt{3} a_i^2 + 2 a_i L_i). \quad (6)$$

424 Accounting for Eq (5), we have

$$425 \quad S = C_k^2 S_r. \quad (7)$$

426 Having obtained the total area, one can calculate SSA as the total surface area of a  
 427 material per unit of mass:

$$428 \quad SSA = \frac{S}{\rho V} = \frac{S_r}{\rho C_k V_r}. \quad (8)$$

429 Comparing SSA of convex particle equal to  $3/\rho r$  with result given by Eq. (8), one can  
 430 easily notice the difference of SSA calculated from different SPS using the same SGS. The  
 431 details of such calculations for other non-convex ice crystal habits are given in the Appendix.

432 The relationship between SSA and SGS for different SPS is presented in Fig. 5. According  
433 to Fig. 5, an almost inverse linear relationship between SSA and SGS can be found. The lines,  
434 representing droxtal, plate, and column, are overlapped, indicating the same SSA for convex  
435 particles. For other SPSs with the same SGS, SSA is larger compared to convex faceted  
436 particles. SSA is restricted in the range of 0-100 m<sup>2</sup>/kg in this investigation (Picard et al.,  
437 2009). For example, for SGS=100μm, the SSA is 32.7 m<sup>2</sup>/kg for convex faceted particles,  
438 whereas SSAs for aggregate of 8 columns, hollow bullet rosettes, hollow column, aggregate of  
439 5 plates, aggregate of 10 plates, and solid bullet rosettes are 44.2, 43.4, 37.7, 74.4, 66.8 and  
440 35.6 m<sup>2</sup>/kg, respectively. The relative differences range from 9%-128%, depending on the SPS.  
441 Taking into account the definition of SSA, one can derive the following relationship between  
442 SSA convex and non-convex particles:  $SSA_{nc} = SSA_c \cdot (A_i/4A_p)$ , where subscript c and nc  
443 denotes convex and non-convex particle, respectively. The obtained results reveal that for all  
444 non-convex ice crystals under consideration  $A_i/4A_p > 1$  and the ratio  $A_i/4A_p$  weakly depends  
445 on the SGS.

446

447

448

449 Fig 5. Relationship between SGS and SSA for different SPS. For a better illustration, the  
 450 realistic range of specific surface area is limited to 100 m<sup>2</sup>/kg.

451

### 452 **5 Impact of model parameters uncertainty**

453 The accuracy of any retrieval algorithm depends not only on measurement errors but also on  
 454 the uncertainty of parameters which cannot be retrieved. In our case, such parameters are ice  
 455 crystal roughness, aerosol, and cloud contamination. The impacts of these factors on XBAER-  
 456 derived SGS and SPS have been investigated and will be discussed in this section. The TOA  
 457 reflectances at selected channels (0.55 and 1.6 μm) and observation directions for SZA, VZA,  
 458 and RAA of 70°, 30°, and 135° for nadir 70°, 55°, and 135° for oblique, respectively, were  
 459 calculated using radiative transfer model SCIATRAN. The details of each scenario will be  
 460 presented in the corresponding sub-section below.

461

462

## 463 **5.1 Impact of snow particle shape**

464 Since the first stage of the XBAER algorithm is to estimate the SGS assuming a given SPS, it  
465 is reasonable to investigate the impact of SPS on the retrieval of SGS. The TOA reflectances  
466 of a snow layer at 0.55 and 1.6  $\mu\text{m}$  with above-given observation geometries were calculated  
467 using the following settings for snow layer and atmospheric parameters:

468 ➤ **Snow Layer:** consists of ice crystals with SPS set to be severely roughened aggregate of  
469 8 columns and maximal dimensions [100, 300, 500, 700, 1000, 2000, 3000, 5000]  $\mu\text{m}$ ,  
470 which corresponds to SGS [15, 45.1, 75.2, 105.3, 150.4, 300.8, 451.3, 752.1]  $\mu\text{m}$ .

471 ➤ **Atmosphere:** excluded

472

473 The simulated snow reflectances were used as components of vector  $\mathbf{A}_e$  in Eq (1). Nine  
474 SPSs from database presented in Yang et al. (2013) are used sequentially in the retrieval process.  
475 The atmospheric correction is not performed because the atmosphere is excluded in the forward  
476 simulations. This enables avoiding additional errors caused by the atmospheric correction and  
477 estimates the pure effect of SPS on the retrieval results. Fig.6 shows the impact of the SPS on  
478 SGS retrieval. Different colors and line styles indicate different ice crystals used in the retrieval  
479 process. The black solid line represents the retrieved SGS assuming SPS in the retrieval process  
480 is the same as in forward simulations. This line agrees well with the 1:1 line, indicating that the  
481 retrieval algorithm has been implemented technically correct. According to Fig.6, one can see  
482 both underestimation and overestimation of SGS depending on the SPS used in retrieval.  
483 However, in most cases, an incorrect SPS leads to an underestimation of SGS. In particular, the  
484 maximal effect can be seen when ice crystals of plate shape, rather than the correct aggregate  
485 of 8 columns, is used (yellow solid line). This result can be easily explained coming back to the  
486 right panel of Fig. 2. Indeed, one can see that the same reflectance of the snow layer can be  
487 obtained using the plate shape, instead of an aggregate of 8 columns, with significantly smaller  
488 SGS. These results reveal that the SPS is an important parameter affecting the accuracy of  
489 retrieved SGS.

Fig 6. Impact of SPS on the retrieval of SGS.

## 5.2 Impact of SGS/SPS on SSA

Since the SSA is obtained from the retrieved SGS and SPS, an understanding of how the error of SGS and/or SPS propagates to the SSA will provide helpful information to understand the retrieved SSA. Fig. 7 shows the impact of SGS (left) and SPS (right) on XBAER retrieved SSA. The relative error of SGS,  $\epsilon_r = (r - r')/r$ , is propagated to the relative error of SSA as  $\epsilon_{SSA} = 1 - 1/(1 - \epsilon_r)$ , and it is independent of reference SSA. The left panel of Fig. 7 depicts  $\epsilon_{SSA}$  corresponding to  $\pm 0.16$  of  $\epsilon_r$ . One can see that this results in 19% and -13.8% of SSA relative errors, which are presented as the upper and lower error boundaries in the left panel of Fig. 7. The systematical error of  $\pm 16\%$  for SGS was obtained as the maximal relative difference between XBAER retrieved SGS and both *in-situ* and aircraft measured SGS (as presented in the companion paper). This represents the worst case of SGS error propagation into SSA.

The impact of SPS on SSA is demonstrated in the right panel of Fig. 7. As a reference shape, we have selected in this case the plate, which provides the same SSA as other convex particles. One can see that the SSA of non-convex particles overestimates the SSA of convex particles, which is in line with the results presented in Section 4. For instance, for the same

508 SGS, the SSA for aggregate 8 columns (non-convex particle) is about 3 times larger than that  
 509 for doxtal (convex particle). Since the assumption of the sphere (convex particle) is used to  
 510 measure SSA in-field measures (Gallet et al., 2009; Personal communication with Dr. Nick  
 511 Rutter), such as observations from SnowEx, the retrieval results of SSA from XBAER will be  
 512 systematically larger than field measurements in the case of non-convex particles even if the  
 513 retrieved and measured SGS are similar. However, a detailed discussion with respect to  
 514 uncertainty in the campaign-based measurement is out of the scope of this manuscript.

515  
 516 Fig 7. Impact of SGS and SPS on the retrieval of SSA. Left panel (SGS errors): the black line  
 517 with dots indicate the 0 difference for accurate SGS for aggregate 8 column, the grey area  
 518 indicate the relative error of SSA introduced by 16% error of SGS; Right panel (SPS selection):  
 519 different color/line styles indicate different SPS used in the calculation of SSA while the true  
 520 SPS is set to be „ plate“ or other convex particles.

521  
 522

### 523 **5.3 Impact of ice crystals surface roughness**

524 Although surface roughness of ice crystal is not so severe for snow compared to ice  
525 cloud due to basic thermodynamics (Colbeck, 1980, 1983), the Ice Crystal Surface  
526 Roughness (ICSR), indicating ice crystal surface texture, may still be important for the retrieval  
527 of snow properties from optical sensors such as SLSTR. The ICSR has been used as a new  
528 variable in model simulation (Järvinen et al., 2018). Retrieval algorithms of ice cloud  
529 parameters frequently based on the assumption that the ice crystal surface is smooth  
530 (Kokhanovsky et al., 2019). This assumption can yet introduce large uncertainty in the ice cloud  
531 retrieval parameters and, as a consequence, lead to misunderstanding the impacts of ice cloud  
532 on global climate change (Järvinen et al., 2018). However, this issue has not yet been discussed  
533 for snow. In general, ice crystal surfaces are rougher in clouds than in snow layers due to  
534 metamorphism processes (Colbeck, 1980, 1983; Ulanowski et al., 2014). The investigation of  
535 the impact of ICSR on retrieval of snow properties provides valuable information to understand  
536 the XBAER algorithm. The ICSR according to Yang et al., (2013) is defined similarly as  
537 suggested by Cox and Munk (1954) for the roughness of the sea surface. A parameter  $\sigma$   
538 describes the degree of ICSR. The  $\sigma$  values 0, 0.03, and 0.5 are for three surface roughness  
539 conditions: smooth, moderate roughness, and severe roughness. And only the above three  
540 values are available in the Yang database. The snow layer reflectances were used as components  
541 of the vector  $\mathbf{A}_e$  in Eq. (1) in the same way as in Section 5.1.

542 Fig. 8 shows the impact of ICRS on the retrieved SGS, SPS, and SSA. The impact of ICRS  
543 on SGS and SSA are relatively small for SGS smaller than  $\sim 300 \mu\text{m}$ . Ignoring the impact of  
544 roughness leads, in general, to a slight overestimation on SGS and an underestimation of SSA.  
545 The absolute errors of SGS and SSA introduced by ICRS range from 0.3% - 3%, depending on  
546 SGS. Due to the inverse almost linear relationship between SSA and SGS, as presented in Fig.  
547 5, for the same SPS, an overestimation of SGS leads to an underestimation of SSA. The slight  
548 overestimation can be found if less ICRS is taken into account in retrieval because the snow  
549 reflectance with the same SGS and SPS for ICRS = 0.5 is larger than for ICRS = 0.03 due to  
550 lower asymmetry factor of ice crystal with more roughened surface roughness, thus the same  
551 surface reflectance observed by satellite requires larger SGS for the case with ICRS = 0.03 used

552 in retrieval in contrast to ICRS = 0.5 used in the forward simulation. However, as can be seen  
 553 from the right panel of Fig.8, the XBAER algorithm still retrieves the correct SPS ignoring the  
 554 impact of roughness.

555  
 556 Fig 8. Impact of Ice Crystal Surface Roughness (ICRS) on the retrieval of SGS (upper left)  
 557 SPS (upper right) and SSA (lower). Different colors indicate different ICSR used in the  
 558 retrieval.

559

#### 560 **5.4 Impact of aerosol contamination**

561 The impact of aerosol on the retrieval of snow properties using passive remote sensing can be  
 562 important because there is limited aerosol information over the cryosphere (Mei et al., 2013a;  
 563 Mei et al., 2013b; Mei et al., 2020a; Tomis et al., 2015) to perform an accurate atmospheric  
 564 correction. The use of MERRA simulated AOT, although with good data quality, will still  
 565 introduce potential aerosol contamination in the XBAER-derived snow properties. The impact  
 566 of aerosol on snow properties retrieval is much smaller over Arctic regions compared to middle-

567 low latitude (e.g. Canadian Arctic, Tibetan Plateau) due to large absolute uncertainty in the  
568 MERRA simulated aerosol over middle-low latitude in wintertime. A detailed comparison of  
569 how possible aerosol contamination may affect the retrieved snow properties will be included  
570 in the companion paper (Mei et al., 2020c). In the companion paper, the comparison between  
571 satellite-derived and campaign-measured snow properties all over the world will be included.  
572 In order to have a better understanding of aerosol contamination on snow properties retrieval,  
573 the TOA reflectances were calculated at 0.55 and 1.6  $\mu\text{m}$  with above-given observation  
574 geometries using the following settings:

575 ➤ **Snow Layer:** Same as in section 5.1;

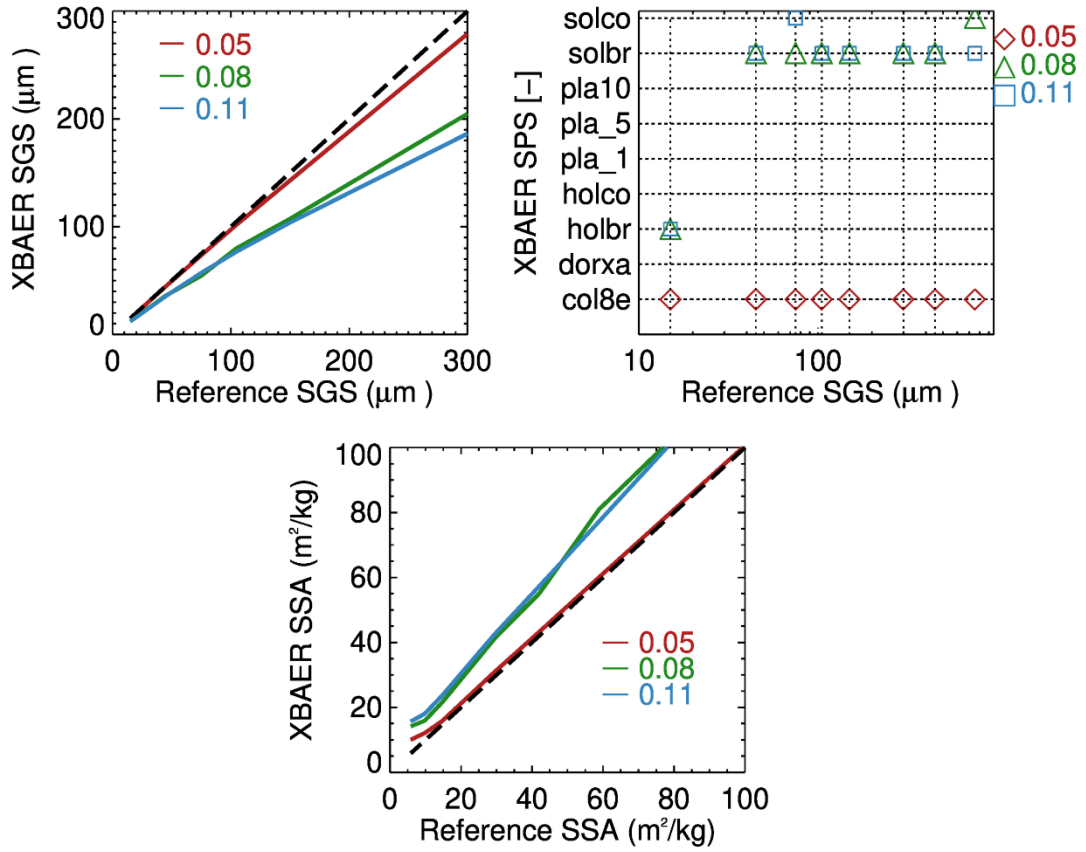

576 ➤ **Atmosphere:**

- 577 ● Aerosol type is set to be weakly absorbing (Mei et al., 2020b) with AOTs [0.05, 0.08, 0.11].  
578 Other atmospheric parameters are set according to Bremen 2D Chemical transport model  
579 (B2D CTM) for April at 75° N (Sinnhuber et al., 2009). It is worth to notice this three AOT  
580 values represent background, average, and pollution conditions in the Arctic as suggested  
581 by Mei et al (2020a; 2020b).

582 Fig.9 shows the impact of aerosol contamination on the SGS (upper left), SPS (upper right),  
583 and SSA (lower) retrieval. These results are obtained by introducing 50% error in AOT at the  
584 step of atmospheric correction and can be considered as the worst case for impact of aerosol  
585 contamination on retrieved SGS, SPS, and SSA. The surface reflectances estimated after  
586 employing the atmospheric correction were used as components of the vector  $\mathbf{A}_e$  in Eq. (1). One  
587 can see that aerosol introduces systematic underestimation of retrieved SGS for the given  
588 scenarios and the magnitude of underestimation increase with the increase of AOT. For a typical  
589 background Arctic aerosol condition, with AOT=0.05, aerosol contamination introduces errors  
590 in SGS of less than 3% for  $\text{SGS} \leq 150 \mu\text{m}$ , and less than 7% for  $150 \leq \text{SGS} < 300 \mu\text{m}$ . The  
591 maximal errors introduced by the aerosol contamination increase to 30% and 37% in the case  
592 of average and pollution conditions for AOT=0.08 and 0.11, respectively. Please be noted that  
593 the AOT values in the Arctic can be even smaller than 0.05, for instance, AOT over Greenland.  
594 Thus, the analysis with respect to aerosol contamination is the worst case for a typical Arctic  
595 condition.

596 For the case of  $AOT = 0.05$ , SPSs have been correctly retrieved for all SGS values,  
597 indicating that under a typical Arctic clean condition, the impact of aerosol is not so large to  
598 disturb SPS retrieval. In order to demonstrate the two stages retrieval process and illustrate the  
599 impact of aerosol, let us focus on Fig. 10. To facilitate the presentation, we consider the  
600 measurement of reflectance at  $1.6 \mu\text{m}$  for a single observation direction ( $30^\circ$ ) and at  $0.55 \mu\text{m}$   
601 for the difference of reflectance at two observation angles ( $30^\circ$  and  $55^\circ$ ). This enables avoiding  
602 the minimization process given by Eq. (1) and represents the retrieval process in the simple  
603 graphic form. The left panel of Fig. 10 depicts the determination of an effective radius for each  
604 ice crystal form, assuming the correct shape is aggregate of 8 columns with an effective radius  
605  $105.4 \mu\text{m}$ . Solid and dotted lines are surface reflectance of the snow layer consisting of ice  
606 crystals with different forms and the dashed line is the measured reflectance after the  
607 atmospheric correction. The obtained SGSs are in the range  $40 - 120 \mu\text{m}$ , depending on the  
608 selected SPS, and presented in Fig. 10 by solid and dotted vertical lines. In the case of correct  
609 SPS selection (aggregate of 8 columns) the retrieved SGS is  $\sim 110 \mu\text{m}$ . The right panel of Fig.  
610 10 shows the second stage of the retrieval process, namely, the selection of such SPS for which  
611 the difference between measured (dashed line) and simulated value (solid black line) is minimal.  
612 In the case under consideration the correct shape is selected with an effective radius  $\sim 110 \mu\text{m}$ .

613 For larger AOT conditions, an inaccurate selection of SPS occurs for all SGS cases,  
614 indicating the remaining aerosol information is large enough to decouple the aerosol  
615 contribution from the snow surface characteristic. Thus, a quality flag of SPS, associated with  
616 AOT, should be introduced in the retrieval of real satellite data. It is interesting to see that “solid  
617 bullet rosettes“ is the preferable SPS for very strong aerosol contamination cases. This is due  
618 to similar scattering properties (shape) of ice crystal and weakly absorbing aerosol, defined in  
619 forward simulation. The impact of aerosol contamination, for typical Arctic conditions,  
620 introduces less than 5% error in SSA. However, for large aerosol contamination, the around 30%  
621 underestimation in SGS linearly introduced about 25% overestimation in SSA, which agrees  
622 with the analysis as presented in Fig.7.

623

## 631 **6 Impact of cloud contamination**

632 Any cloud screening method, especially over the cryosphere, may introduce cloud  
633 contamination for the retrieval of atmospheric and surface properties (Chen et al., 2014; Mei et  
634 al., 2017; Jafariserajehlou et al., 2019). Understanding of the cloud contamination will  
635 provide valuable information to interpret the retrieval results using the SLSTR instrument. To  
636 investigate the impact of cloud contamination, the following settings were used to perform the  
637 simulations of TOA reflectance:

638 ➤ **Snow Layer:** Same as section 5.1;

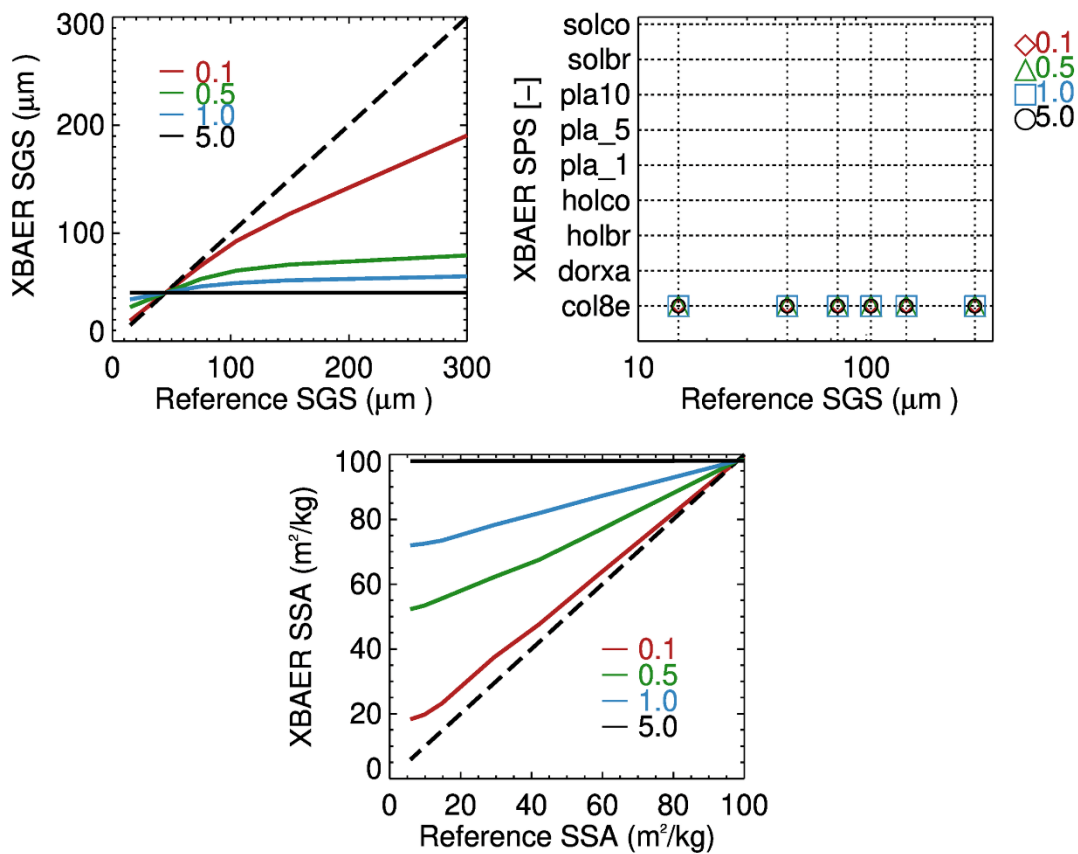

639 ➤ **Atmosphere:** Aerosol free atmosphere with other parameters as in section 5.4.  
640 Additionally, vertically homogeneous ice cloud consisting of aggregate of 8 columns with  
641 effective radius of 45  $\mu\text{m}$  and optical thickness [0.1, 0.5, 1.0, 5] is set to be at position of  
642 [5 km, 6 km].

643 Fig. 11 shows the impact of cloud contamination on XBAER retrieved SGS (upper left),  
644 SPS (upper right), and SSA (lower). The size of ice crystals in ice clouds is typically smaller  
645 than snow grain size (Kikuchi et al., 2013). Our statistical analysis of ice crystal effective radius  
646 over Greenland shows an average value in the range of 30-50  $\mu\text{m}$ , which is consistent with  
647 previous publications (King et al., 2013; Platnick et al., 2017). According to Fig.11, an  
648 overestimation of SGS can be found for SGS less than 45 $\mu\text{m}$  (cloud effective radius) and an  
649 underestimation of SGS for SGS larger than 45 $\mu\text{m}$ . The magnitude of  
650 overestimation/underestimation increases with the increase of Cloud Optical Thickness (COT).  
651 XBAER derived SGS becomes saturated for COT larger than 0.5. Due to limited photon  
652 penetration depth for optically thicker clouds (e.g., COT = 5), the XBAER algorithm retrieves  
653 the effective radius of ice crystal in the cloud. This demonstrates that theoretically, the XBAER  
654 algorithm can retrieve an ice cloud effective radius without a pre-processing of cloud screening.  
655 And this can be further used as post-processing to avoid cloud contamination.

656

657 The impact of the cloud on the retrieval of SPS is similar to the impact of aerosol  
 658 considered above. In short, the cloud plays a larger role for larger SPS (darker TOA) and this  
 659 impact increases with the increase of COT. However, cloud with large COT can be much easier  
 660 detected and excluded by the cloud screening algorithm (e.g for the cases with COT > 0.5).  
 661 SPSs are correctly picked up due to the same SPS used for both the snow layer and the cloud  
 662 layer. Similar to the impact of aerosol, the underestimation of SGS introduced by the cloud  
 663 leads to an overestimation of SSA (Fig. 11 (lower panel)). The increase of COT results in  
 664 saturation of the ice cloud SSA, with a value of 100 m<sup>2</sup>/kg in the case of aggregate of 8 columns.

665

666  
 667 Fig 11. Impact of cloud contamination on the retrieval of SGS (upper left) SPS (upper right)  
 668 and SSA (lower). Different colors indicate different COTs in forward simulations, black dash  
 669 line is the 1:1 line.

670

## 671 **7 Impact of other factors occurring in reality**

672 The above theoretical investigations include all possible important factors affecting the  
673 accuracy XBAER algorithm. However, when applying XBAER algorithm to the SLSTR  
674 instrument for real scenarios, two additional factors need to be considered as well. One is the  
675 impact of the instrument spectral response function (SRF), the other one is the  
676 representativeness of the snow scenario for reality.

### 677 **7.1 Impact of instrument spectral response function**

678

679 ➤ **Snow Layer:** Same as section 5.1;

680 ➤ **Atmosphere:** Aerosol free atmosphere with other parameters as in section 5.4.

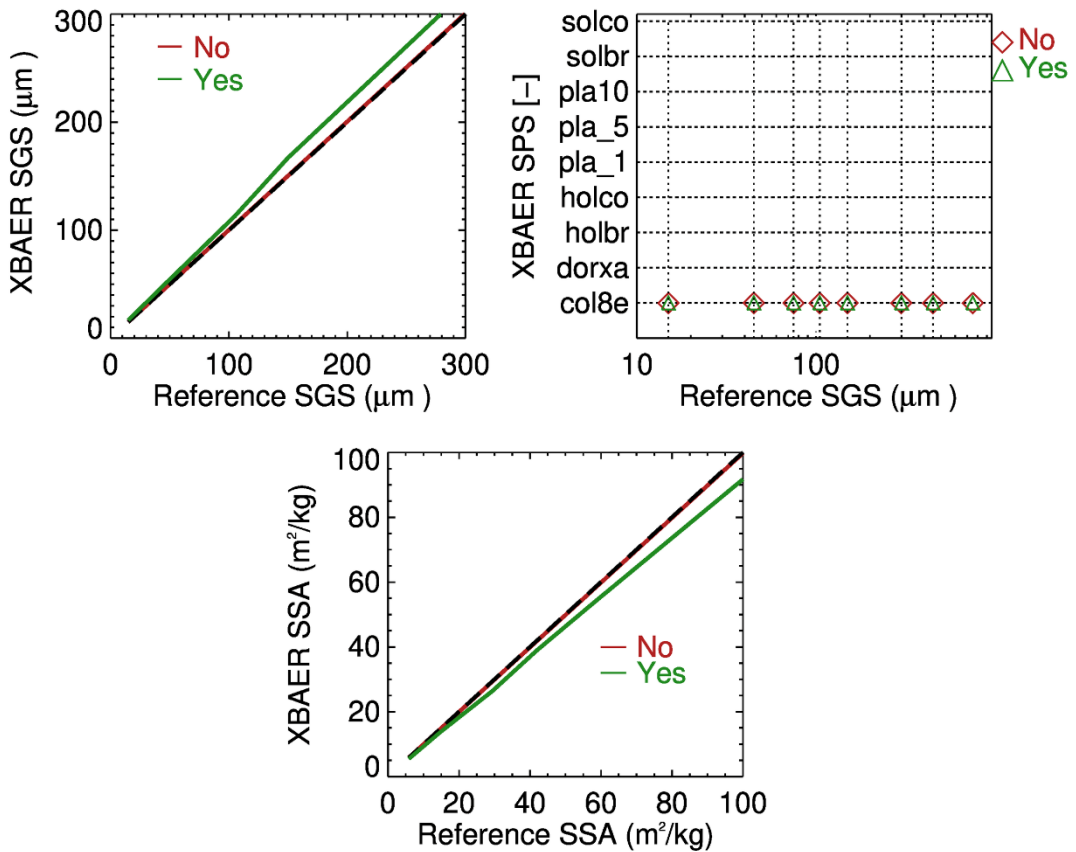

681

682 The forward simulations are performed with and without the impact of Spectral Response  
683 Function (SRF). The SRFs for SLSTR at 0.55 and 1.6  $\mu\text{m}$  are shown in Fig. 12. The retrieval  
684 is then performed ignoring SRF. Fig. 13 shows the impact of SRF on the retrieval of SGS, SPS,  
685 and SSA. For forward simulations without taking SRF into account (labeled as No in Fig. 13),  
686 SGS, SPS, and SSA are well received as expected. And it agrees with Fig. 6. However, ignoring  
687 the impact of SRF introduces about 7% uncertainties in the simulated surface reflectance and  
688 this causes about 5-7% error in both SGS (overestimation) and SSA (underestimation). Taking  
689 SRF into account leads to a smaller surface reflectance at 1.6  $\mu\text{m}$  due to potential gas absorption  
690 at this wavelength, thus introduces an overestimation for SGS. However, due to a significantly  
691 smaller impact at 0.55  $\mu\text{m}$ , the SRF does not play a significant role in the retrieval of SPS.

692  
693  
694

698 Different colors indicate retrieval results without (No) and with (Yes) SRF in forward

699 simulations, black dash line is the 1:1 line.

700

701

## 702 **7.2 Impact of snow inhomogeneities**

703 In this section, a realistic model of snow layer is represented by vertically inhomogeneous,  
704 polydisperse ice crystals habit mixture. Following Saito et al (2019), the gamma distribution  
705 with respect to the maximal dimension will be used to describe polydisperse properties:

$$706 \quad n(D) = NG(D), \quad (9)$$

707 Here, N is the number of ice particles per unit volume, G(D) is the gamma distribution function,  
708 i.e.,

$$709 \quad G(D) = C(D/v)^{k-1} e^{-D/v}, \quad (10)$$

710 where k and v are the shape and scale parameters, normalization factor C is defined as

$$711 \quad C = \left[ \int_{D_{\min}}^{D_{\max}} (D/v)^{k-1} e^{-D/v} dD \right]^{-1},$$

712 (11)

713  $D_{\min}$  and  $D_{\max}$  describe the minimal and maximum particle sizes in the distribution.

714 In order to introduce the vertical inhomogeneity, we use the measurement of snow density and  
715 equivalent optical diameter vertical profiles conducted during the SnowEx17 campaign.  
716 Accounting for that the equivalent optical diameter cannot be directly used to define parameters  
717 of Gamma distribution, we use the vertical profile as a shape of the mode (most frequent value  
718 in a dataset), i.e.

$$719 \quad D_0(z) = \frac{D_e(z)}{D_e(z_{top})} D_0(z_{top}), \quad (12)$$

720 where  $D_e(z)$  is the measured vertical profile of equivalent optical diameter,  $D_0(z)$  is the vertical  
721 profile of the mode. The mode near the top of snow layer,  $D_0(z_{top})$ , we assume to be equal 400  
722  $\mu\text{m}$  according to the measurement data reproduced by Saito et al (2019) in Fig. A1.

723 Taking into account the analytical expression of the mode via shape and scale parameters,

$$724 \quad D_0 = (k-1)v. \quad (13)$$

725 and the following relationship between shape and scale parameters derived by Saito et al (2019):

$$726 \quad k = 11.38v^{-0.167} - 2. \quad (14)$$

727 we can estimate parameters  $k$  and  $v$  of Gamma distribution corresponding to  $D_0(z)$  given by Eq  
728 (12).

729 Snow Grain Habit Mixture (SGHM) model is used according to Saito et al (2019). In  
730 particular, the particle habits include droxtal, solid hexagonal column, and solid bullet rosette.  
731 Habit fraction,  $f_h(D)$ , as a function of maximal dimension of the SGHM model is presented in  
732 the right panel of Fig. 14. The habit fraction is defined so that ,for each  $D$ ,

$$733 \quad \sum_{h=1}^3 f_h(D) = 1. \quad (15)$$

734 The selected SGHM model enables us to derive the total volume of ice per unit volume of  
735 air as

$$736 \quad V_i = N \sum_{h=1}^3 \left[ \int_{D_{\min}}^{D_{\max}} V_h(D) f_h(D) G(D) dD \right], \quad (16)$$

737 and ice water content (IWC)

$$738 \quad IWC = V_i \rho_{ice}, \quad (17)$$

739 where  $V_h(D)$  is the volume of each habit as given in database of Yang and  $\rho_{ice}$  is the density of  
740 ice.

741 Taking into account that the vertical profile of IWC is measured (see right panel of Fig.  
742 13), we can obtain the vertical profile of particle number density. Using Eqs (16) and (17), we  
743 have

$$744 \quad N(z) = \frac{IWC(z)}{\rho_{ice} \sum_{h=1}^3 \left[ \int_{D_{\min}}^{D_{\max}} V_h(D) f_h(D) G(D, z) dD \right]}. \quad (18)$$

745 Summing up, we define the microphysical properties of snow layer using the following  
746 model of particle size distribution

747 
$$n(D, z) = N(z)C \left[ \frac{(\bar{k} - 1)D}{D_0(z)} \right]^{\bar{k}-1} \exp \left[ -\frac{(\bar{k} - 1)D}{D_0(z)} \right], \quad (19)$$

748 where  $D_0(z)$  and  $N(z)$  are given by Eq (12) and (18), respectively, shape parameter,  $k$ , is  
 749 assumed to be altitude independent and set to 2.3.

750 The bulk single-scattering properteis of snow layer such as extinction coefficent,  
 751 scattering coefficient and scattering function are defined by the same way as proposed by Baum  
 752 et al. (2011). For instance, the bulk extinction coefficient is calculated as

753 
$$\beta_{ext}(z) = \int_{D_{min}}^{D_{max}} \left[ \sum_{h=1}^3 \sigma_{ext,h}(D) f_h(D) n(D, z) dD \right], \quad (20)$$

754 where  $\sigma_{ext,h}(D)$  is the extinction cross-section as given for each habit in database of Yang et  
 755 al.

756

757

758 Fig. 13 Snow properties used for simulations to investigate the impacts of snow layer  
 759 model on XBAER retrieval (left) snow grain size profile and (right) snow density observed  
 760 during SnowEx17 campaign

761  
 762 Fig. 14 Snow properties used for simulations to investigate the impacts of habit mixture  
 763 model on XBAER retrieval: (left) particle size distribution of snow grain size in snow layer;  
 764 (right) habit fraction suggested by Saito et al (2019)

765 The following settings are used to simulate the reference snow reflectance at wavelengths  
 766 0.55 and 1.6  $\mu\text{m}$ ;

- 767 ➤ **Snow Layer:** vertically inhomogeneous, polydisperse habit mixture and model as
- 768 described above;
- 769 ➤ **Atmosphere:** excluded.

770 Using the simulated reflectances in XBAER algorithm, we have retrieved SPS as dorxtal  
 771 with the maximal dimension equal to 740  $\mu\text{m}$ . Taking into account that the model of PSD near  
 772 the top of snow layer is 400  $\mu\text{m}$  and the mean value calculated as  $kD_0/(k-1)$  is equal to 708  $\mu\text{m}$ ,

773 one can see that the retrieved maximal dimension is an estimation of mean value of PSD near  
 774 the top of snow layer.

775 Since there is no single reference SGS values when a PSD is used, it is important to check  
 776 the representativeness of XBAER derived SGS. Accounting for that the mode and mean values  
 777 for a given PSD are two typical “effective” way to describe polydisperse medium, we compared  
 778 reflectances of snow layer calculated assuming PSD in the form of Gamma distribution and  
 779 assuming monodisperse medium with SGS equal to the mode or to the mean of selected PSD.  
 780 In order to simplify analysis, we consider vertically homogeneous snow layer consisting of only  
 781 single particle habit. The calculations of reflectance were performed for severely roughened  
 782 aggregate of 8 columns and droxtal particles setting the shape parameter,  $k$ , equal to 2.3 and  
 783 the model equal to [100, 300, 500, 700, 1000, 2000, 3000, 5000]  $\mu\text{m}$ .

784 Fig. 15 shows the comparison of snow reflectance calculated assuming monodisperse and  
 785 polydisperse snow model. In the case of monodisperse model, SGS is assumed to be equal to  
 786 the mean or to the mode value of PSD. We can see that the surface reflectance calculated using  
 787 the mean value of PSD agrees better with reference values, than reflectance calculated using the  
 788 mode value. In particular, the root-mean-square deviation (RMSE) values are more than 2 times  
 789 smaller. One can also see from Fig. 15 that the difference between monodisperse reflectances  
 790 calculated using mean or mode PSD values decreases with increase of the PSD mode. It can be  
 791 explained due to the fact that the increase of PSD mode leads to the increase of absorption and  
 792 decrease of reflectance sensitivity with respect to the variation of SGS.

793

794 Fig. 15 The comparison between simulated snow reflectance using mono and poly-disperse  
795 snow model consisting of aggregate of columns (left) and droxtal (right). In the case of  
796 monodisperse model, the SGS is assumed to be the mean and mode value of PSD at the top of  
797 snow layer (see left panel of Fig. 14). The reference value is shown on the x-axis.

798

## 799 **8 Conclusions**

800 SGS, SPS, and SSA are three important parameters to describe snow properties. They play  
801 important roles in the changes in snow albedo/reflectance and impact the atmospheric and  
802 energy-exchange processes. A better knowledge of SGS, SPS, and SSA can provide more  
803 accurate information to describe the impact of snow on Arctic amplification processes. The  
804 information about SGS, SPS, and SSA may also explore new applications to understand the  
805 atmospheric conditions (e.g. aerosol loading). Although some previous attempts (e.g. Lyapustin  
806 et al., 2009) show the capabilities of using passive remote sensing to derive SGS over a large  
807 scale, no publication has been found to derive SGS, SPS, and SSA simultaneously. To our best  
808 knowledge, this is the first paper, attempting to retrieve these parameters using satellite  
809 observations.

810 The new algorithm is designed within the framework of the XBAER algorithm. The  
811 XBAER algorithm has been applied to derive SGS, SPS, and SSA using the newly launched  
812 SLSTR instrument onboard Sentinel-3 satellite. This is the first part of the paper, to describe  
813 the algorithm, and to present the sensitivity studies.

814 The SGS, SPS, and SSA retrieval algorithm is based on the recent publication by Yang et  
815 al., (2013), in which a database of optical properties for nine typical SPSs (aggregate of 8  
816 columns, droxtal, hollow bullet rosettes, hollow column, plate, aggregate of 5 plates, aggregate  
817 of 10 plates, solid bullet rosettes, column) are provided. Previous publications show that this  
818 database can be used to retrieve ice crystal properties in both ice cloud and snow (e.g., Järvinen  
819 et al., 2018; Saito et al., 2019). The algorithm is a LUT-based approach, in which the  
820 minimization is achieved by the comparison between atmospherically corrected TOA  
821 reflectance at 0.55 and 1.6  $\mu\text{m}$  observed by SLSTR and pre-calculated LUT of surface

822 reflectances under different geometries and snow properties. The retrieval is relatively time-  
823 consuming because the minimization has to be performed for each SPS and the optimal SGS  
824 and SPS are selected after 9 minimizations are done. The SSA is then obtained using the  
825 retrieved SGS and SPS based on another pre-calculated LUT.

826 The sensitivity studies with respect to the impacts of SPS, ICSR, aerosol and cloud  
827 contamination on XBAER derived SGS and SPS provide a comprehensive understanding of  
828 the retrieval accuracy of the new algorithm. The main findings of the theoretical considerations  
829 are: (1) XBAER derived SGS is more likely to represent the average SGS near the top of snow  
830 layer when a PSD is known; (2) SPS plays an important role for the retrieval accuracy of SGS,  
831 the retrieved SGS can differ several times by usage different SPSs in the retrieval process; (3)  
832 Impact of ICSR on the retrieval accuracy of SGS can be neglected, ignoring ICSR completely  
833 may introduce maximal 3% error on the retrieval accuracy of SGS, especially for large ice  
834 crystals; (4) Assumption of convex particle shape (e.g., sphere) of a non-convex ice crystal  
835 leads to the underestimation of the retrieved SSA; (5) The impact of aerosol and cloud increase  
836 with the increase of both aerosol/cloud loading and SGS; (6) The impact of instrument SRF  
837 may introduce some positive bias for SGS and negative bias for SSA, however, it plays no  
838 role for the determination of SPS

839 Even though all major possible factors affecting the retrieval accuracy of XBAER  
840 algorithm are investigated in this paper, in reality, the final retrieval accuracy can only be  
841 evaluated by performing a thorough comparison with independent measurement results because  
842 uncertainties caused by each individual factor can compensate each other in the real satellite  
843 retrieval. All details of such validation can be found in the companion paper of Mei et al (2020c).

850

## 851 **Appendix**

852 According to the definition of specific surface area

$$853 \quad SSA = \frac{A}{\rho V}, \quad (A1)$$

854 one needs to calculate the total area A of ice crystal. In the following sections, we consider  
855 in details the basic equations to calculate total area and SSA of different SPSs given in  
856 database of Yang et al (2013) and used above within the retrieval algorithm.

857

### 858 ➤ **Droxtal, solid column, plate**

859 In the case of convex faceted particles such as droxtal, solid column, and plate, the  
860 calculation of total area is straightforward and based on the Cauchy's surface area formula:

$$861 \quad A = 4A_p. \quad (A2)$$

862 Taking into account that for selected SPS, one can find corresponding V and  $A_p$  in database  
863 given by Yang et al., (2013), we have the following results for SSA of such particles:

$$864 \quad SSA = \frac{4A_p}{\rho V}. \quad (A3)$$

### 865 ➤ **Hollow column**

866 In this case a solid column includes two equal cavities in the form of a hexagonal  
867 pyramid and cannot be considered as convex particle. The aspect ratio of hollow column  
868 with the height, d, of hexagonal pyramid is given according to Yang et al., (2013) as:

$$869 \quad \frac{2a}{L} = \begin{cases} 0.7, & L < 100 \mu m \\ \frac{6.96}{\sqrt{L}}, & L \geq 100 \mu m \end{cases}, \quad d = 0.25L. \quad (A4)$$

870 The volume of such hollow column is given by

871 
$$V = V_c - 2V_p, \tag{A5}$$

872 where the volume of solid column,  $V_c$ , and a hexagonal pyramid,  $V_p$ , are,

873 
$$V_c = \frac{3\sqrt{3}}{2} a^2 L, \tag{A6}$$

874 
$$V_p = \frac{\sqrt{3}}{2} a^2 d. \tag{A7}$$

875 Thus, the volume,  $V$ , is

876 
$$V = \frac{\sqrt{3}}{2} a^2 (3L - 2d). \tag{A8}$$

877 Employing the relationship between  $d$  and  $L$  given by Eq (A4) and excluding  $a$ , we  
878 have

879 
$$V = \frac{2.5\sqrt{3}}{2} a^2 L \begin{cases} m_0 m_1^2 L^3, & L < 100 \mu m \\ m_0 m_2^2 L^2, & L \geq 100 \mu m \end{cases} \tag{A9}$$

880 where  $m = \frac{2.5}{\sqrt{3}/2}$ ,  $m_1 = \frac{0.7}{2}$ , and  $m = \frac{6.96}{2}$ . For a selected volume,  $V$ , the length,

881  $L$ , is calculated as follows:

882 
$$L = \begin{cases} [V / m_0 / m_1^2]^{\frac{1}{3}}, & V < V_{100} \\ [V / m_0 / m_2^2]^{\frac{1}{2}}, & V \geq V_{100} \end{cases}, \tag{A10}$$

883 where  $V_{100} = m_0 m_2^2 100^2$ .

884 Let us now calculate the area of each triangle side of the pyramid

885 
$$S_i = \frac{a}{2} \sqrt{d^2 + \frac{3a^2}{4}}. \tag{A11}$$

886 The area of lateral surface of two pyramids is

$$887 \quad S_p = 3a\sqrt{4d^2 + 3a^2}.$$

888 (A12)

889 And the total surface area of hollow column is given by

$$890 \quad S = 6aL + 3a\sqrt{4d^2 + 3a^2}, \quad (A13)$$

891 where  $a$  and  $d$  should be expressed via  $L$  according to Eq. (A4).

892 Having obtained the total area, one can calculate specific surface area

$$893 \quad SSA = \frac{S}{\rho V}, \quad (A14)$$

894 ➤ **Hollow bullet rosettes**

895 In this case a solid column includes a cavity in the form of a hexagonal pyramid with  
896 height  $H$  and a hexagonal pyramid with height  $t$  on the opposite site of column. The aspect  
897 ratio and parameters  $H$  and  $t$  is given according to Yang et al., (2013) as:

$$898 \quad \frac{2a}{L} = 2.3104L^{-0.37}, \quad t = \frac{\sqrt{3}a}{2 \tan(28^\circ)}, \quad H = 0.5(t + L). \quad (A15)$$

899 The volume of a hollow bullet rosettes is given by

$$900 \quad V_1 = V_c - V_- + V_+. \quad (A16)$$

901 Using Eq. (A16), we have

$$902 \quad V_1 = \frac{3\sqrt{3}}{2}a^2L - \frac{\sqrt{3}}{2}a^2H + \frac{\sqrt{3}}{2}a^2t = \frac{\sqrt{3}}{2}a^2(3L - H + t). \quad (A17)$$

903 Substituting  $H$  as given by Eq (A15), we obtain

904 
$$V_1 = \frac{\sqrt{3}a^2}{4}(5L+t). \quad (\text{A18})$$

905 Using formula given by Eq (A15), we express parameters  $a$  and  $t$  of hollow bullet  
906 rosettes via  $L$ :

907 
$$a = m_a L^{p_a}, \quad (\text{A19})$$

908 
$$t = m_t m_a L^{p_a}, \quad (\text{A20})$$

909 where coefficients,  $m_a$ ,  $m_t$ , and  $p_a$  are

910 
$$m_a = \frac{2.3104}{2}, m_t = \frac{\sqrt{3}}{2 \tan(28^\circ)}, p_a = 1 - 0.37.$$

911 (A21)

912 The expression (A18) can be rewritten as:

913 
$$V_1 = \frac{3}{4} m_a^2 L^{2p_a+1} (5 + m_t m_a L^{-0.37}). \quad (\text{A22})$$

914 For a desired volume  $V$  of hollow bullet rosettes, consisting of 6 equal rosettes  
915 (See Table 1), this equation was solved with respect to the length,  $L$ , of the hollow bullet  
916 rosette using following iterative process:

917 
$$L_n = \left[ \frac{2V}{3\sqrt{3}m_a^2 (5 + m_t m_a L_{n-1}^{-0.37})} \right]^{\frac{1}{2p_a+1}}. \quad (\text{A23})$$

918 The iterative process starts with  $L_0=1$  and finishes when  $\left| \frac{L_n - L_{n-1}}{L_n} \right| \leq 10^{-4}$ . The total

919 area of hollow bullet rosettes is calculated as;

920 
$$S_1 = 6aL + \frac{3a}{2} \sqrt{4H^2 + 3a^2} + \frac{3a}{2} \sqrt{4t^2 + 3a^2}. \quad (\text{A24})$$

921 The SSA is given by

922 
$$SSA = \frac{6S_1}{\rho V}. \quad (A25)$$

923 ➤ **Solid bullet rosettes**

924 The aspect ratio and parameter  $t$  are given according to Yang et al., (2013) as:

925 
$$\frac{2a}{L} = 2.3104L^{-0.37}, \quad t = \frac{\sqrt{3}a}{2 \tan(28^\circ)}. \quad (A26)$$

926 The volume of single solid bullet rosette is

927 
$$V_1 = V_c + V_+. \quad (A27)$$

928 Using Eq. (A6), we have

929 
$$V_1 = \frac{3\sqrt{3}}{2} a^2 L + \frac{\sqrt{3}}{2} a^2 t = \frac{\sqrt{3}}{2} a^2 (3L + t). \quad (A28)$$

930 Using formula given by Eq (A26), we express parameters  $a$  and  $t$  of solid bullet rosette  
931 via  $L$ :

932 
$$a = m_a L^{p_a}, \quad (A29)$$

933 
$$t = m_t m_a L^{p_a}, \quad (A30)$$

934 Where coefficients,  $m_a$ ,  $m_t$ , and  $p_a$  are the same as in the case of hollow bullet  
935 rosette given by Eq. (A21). The expression Eq. (A28) can be rewritten as

936 
$$V_1 = \frac{3}{2} m_a^2 L^{2p_a+1} (3 + m_t m_a L^{-0.37}). \quad (A31)$$

937 For a desired volume  $V$  of solid bullet rosettes, consisting of 6 equal rosettes (see  
938 Table 1), this equation was solved with respect to the length,  $L$ , of the solid bullet rosette  
939 using following iterative approach:

940 
$$L_n = \left[ \frac{V}{3\sqrt{3}m_a^2(3 + m_t m_a L_{n-1}^{-0.37})} \right]^{\frac{1}{2p_a+1}}. \quad (\text{A32})$$

941 The total area of solid bullet rosettes is calculated as;

942 
$$S_1 = 6aL + \frac{3\sqrt{3}a^2}{2} + \frac{3a}{2}\sqrt{4t^2 + 3a^2}. \quad (\text{A33})$$

943 The SSA is given by

944 
$$SSA = \frac{6S_1}{\rho V}. \quad (\text{A34})$$

945

946 ➤ **Aggregate of 5 and 10 plates**

947 According to the paper of Yang et al (2013), Table 1 provides the aspect ratios of the  
 948 ice crystal habits. In the case of an aggregate of columns or plates, the semi-width  $a$  and  
 949 length  $L$  of each hexagonal element of the aggregate are on a relative scale. In order to covert  
 950 these parameters in absolute values, let us consider the following relationship given in Yang  
 951 et al (2013) for aspect ratio of plate:

952 
$$\frac{2a}{L} = \begin{cases} 1, & a \leq 2\mu m \\ m_1 a + m_0, & 2 < a < 5\mu m \\ m a^p, & a \geq 5\mu m \end{cases} \quad (\text{A35})$$

953 where constants are:  $m_1=0.2914$ ,  $m_0=0.4172$ ,  $m=0.8038$ ,  $p=0.526$ .

954 Using this expression and accounting for that relative values for  $a$ , given in Table 1, are  
 955 greater than  $5\mu m$ , we can express  $L_r$  via  $a_r$  as

956 
$$L_r = \frac{2a_r}{m a_r^p} = \frac{2a_r^{1-p}}{m}. \quad (\text{A36})$$

957 where subscript  $r$  denotes that they are on relative scale. The volume of a hexagonal plate on  
 958 relative scale is given by

959 
$$v_r = \frac{3\sqrt{3}}{2} a_r^2 L_r = \frac{3\sqrt{3}}{m} a_r^{3-p}. \quad (\text{A37})$$

960 The volume of aggregates of 5 or 10 plates is given by

961 
$$V_r = \frac{3\sqrt{3}}{m} \sum_{i=1}^N a_{r,i}^{3-p}, \quad (\text{A38})$$

962 where  $N=5$  and  $N=10$  for 5 and 10 plates, respectively. The absolute value of the volume,  
 963  $V$ , for a selected maximal dimension of aggregate of 5 or 10 plates one can find in database  
 964 presented by Yang et al (2013). Introducing the scaling factor

965 
$$C = \frac{V_r}{V}, \quad (\text{A39})$$

966 We rewrite expression (A38) as

967 
$$C = \frac{V_r}{C} = \frac{3\sqrt{3}}{mC} \sum_{i=1}^N a_{r,i}^{3-p} = \frac{3\sqrt{3}}{m} \sum_{i=1}^N a_i^{3-p}, \quad (\text{A40})$$

968 where the absolute value of semi-width,  $a_i$ , is given by

969 
$$a_i = \frac{a_{r,i}}{C^{(3-p)^{-1}}}, \quad (\text{A41})$$

970 Having obtained the absolute value of  $a_i$  for each plate, the length  $L_i$  is calculated as:

971 
$$L_i = \begin{cases} 2a_i, & a \leq 2\mu\text{m} \\ \frac{2a_i}{m_1 a_i + m_0}, & 2 < a < 5\mu\text{m} \\ \frac{2}{m_1 a^{(1-p)}}, & a \geq 5\mu\text{m} \end{cases} \quad (\text{A42})$$

972

973 The total area of a hexagonal plate with semi-width  $a_i$  and length  $L_i$  is given by

974 
$$S_i = 2 \frac{3\sqrt{3}}{2} a_i^2 + 6a_i L_i, \quad (\text{A43})$$

975 The total area is given by

976 
$$S = \sum_{i=1}^N S_i. \quad (\text{A44})$$

977 Having obtained the total area, one can calculate SSA as the total surface area of a material per  
 978 unit of mass:

979 
$$SSA = \frac{S}{\rho V}, \quad (\text{A45})$$

980 where  $\rho=917 \text{ kg/m}^3$  is the density of ice.

981
